## Summary

The NF- $\kappa$ B/Rel signalling pathway plays a crucial role in numerous biological processes, including innate and adaptive immunity. Although the cytoplasmic regulation of NF- $\kappa$ B is well characterised, its nuclear regulation mechanisms is only recently started to become elucidated. The nuclear I $\kappa$ Bs contribute significantly to the modulation of NF- $\kappa$ B activity. I $\kappa$ B<sub>NS</sub>, an atypical I $\kappa$ B protein, regulates the proliferation of T and B cells. Furthermore, the expression of various cytokines is modulated via I $\kappa$ B<sub>NS</sub> by its ability to specific activation or termination of NF- $\kappa$ B function at certain cytokine promoters. The aim of this thesis was to obtain a better understanding of the role of I $\kappa$ B<sub>NS</sub> during the regulation of NF- $\kappa$ B activity in health and disease.

The activation of the TCR rapidly induces I $\kappa$ B<sub>NS</sub> expression. However, it is unknown if I $\kappa$ B<sub>NS</sub> itself affects this activation cascade or if it modulates the expression of NF- $\kappa$ B subunits. Analysis of CD4<sup>+</sup> T cells *ex vivo* revealed that I $\kappa$ B<sub>NS</sub> does neither affect the proximal TCR signalling nor the expression of NF- $\kappa$ B subunits upon cell activation. The nuclear I $\kappa$ B protein I $\kappa$ B $\zeta$  regulates the proliferation of T<sub>H</sub>17 cells as well as the expression of IL17A. This thesis uncovered I $\kappa$ B<sub>NS</sub> as a second I $\kappa$ B protein intrinsically involved in the development of T<sub>H</sub>17 cells. In addition, *in vitro* experiments revealed that I $\kappa$ B<sub>NS</sub> regulates the expression of IL10 in T<sub>H</sub>17 cells. In *in vivo* experiments, I $\kappa$ B<sub>NS</sub> seems to be almost dispensable for the course of EAE. In contrast, in the colitis models I $\kappa$ B<sub>NS</sub>-deficient mice suffered from more severe inflammation of the gut and were more susceptible to *Citrobacter rodentium* infections. Additionally, I $\kappa$ B<sub>NS</sub> was crucial for the formation of T<sub>H</sub>1 and T<sub>H</sub>7 cells in gut inflammation as well as infection. Furthermore, the induction of T<sub>H</sub>17 cell was modulated by I $\kappa$ B<sub>NS</sub>, while it was less important for T<sub>H</sub>1 cell development during inflammation and infection of the gut.

In this thesis was demonstrated that I $\kappa$ B<sub>NS</sub> does not only regulate the transition of immature Treg precursor into immuno-suppressive Treg cells, but is also necessary for the generation of pro-inflammatory T<sub>H</sub>17 cells *in vitro* and *in vivo*. Thus, I $\kappa$ B<sub>NS</sub> exhibits diverse regulatory functions for T cell proliferation and cytokine secretion. Consequently, I $\kappa$ B<sub>NS</sub> may represent a T cell specific pharmacological target in the future.

# 1 Introduction

## 1.1 The key players of the immune system

From birth, the immune system is constantly exposed to a rich diversity of microorganisms. For example 100 trillion microorganisms, composed of 500 to 5,000 different species are present in the human intestine<sup>1-3</sup>. Nevertheless, most of the organisms within the intestinal tract are well-tolerated because of mutual benefits. The human intestine offers a relatively stable environment, well-tempered and nutrient-rich, to the commensal bacteria. In turn, human benefits from an increased digestive capacity and increased protection against pathogenic organisms<sup>1,3,4</sup>. During the course of life, a disruption of this balance by changes of diet, antibiotic treatment or invasion of pathogens can result in immune-mediated diseases. For instance inflammatory bowel diseases (IBD), like Crohn's disease and ulcerative colitis are linked to a dysregulated intestinal micro-environment. Furthermore, experimental autoimmune encephalomyelitis (EAE)<sup>5,6</sup>, rheumatoid arthritis<sup>7</sup> and diabetes<sup>8</sup> have also been suggested to be associated with a change of the commensal gut flora. Therefore, the immune system needs to tolerate commensal organisms as well as self-antigens, but has to defend the body from pathogenic microorganisms from outside and tumours from the inside.

During evolution, vertebrates developed the adaptive immune system in addition to innate immune responses. This was an essential step, because both, the rapidity of the innate and the diversity of the adaptive immune response are crucial for effective protection of the human organism<sup>9</sup>. The innate immune system of the vertebrates is able to recognise conserved pathogen-associated molecular pattern (PAMPs) of invading microorganisms. This is possible via the pattern recognition receptors (PRR) of cells of the innate immune system. Thereby, innate immune cells distinguish pathogenic components and harmless antigens<sup>2,4,10</sup>. Thus, antigen-presenting cells (APCs) recognise and engulf pathogenic microorganisms. Afterwards, APCs degrade and process the microbial proteins intracellularly and subsequently the foreign antigens are presented via the major histocompatibility complex (MHC) class II<sup>10</sup>. Additionally, the transcription factor nuclear factor-kappa B (NF- $\kappa$ B) becomes activated by the recognition of pathogens followed by cytokine expression and up-regulation of co-stimulatory molecules on APCs in peripheral lymphoid organs. The produced cytokines attracts T and B cells, which are parts of the adaptive immune response, thereby creating a link between innate and adaptive immunity.<sup>4,10</sup> Naïve T cells recognise the APC-bound non-self antigen via their T cell

receptor (TCR). The recognition of the cognate antigen together with the binding of co-stimulatory molecules of the APC activates the T cell and initiates a new gene expression program. This initiates an expansion phase of T cells. Within this phase T cells start to proliferate and finally differentiate into effector T cells, which migrate to the infected areas of the body. When all pathogens/ antigens have been cleared, the immune system enters the contraction phase. Within this phase most of the effector cells die by apoptosis to return to homeostasis. The surviving cells differentiate into long-lasting memory cells, which are available for a faster and stronger response the next time the immune system is challenged with this specific pathogen. <sup>11,12</sup>

## 1.2 Thymic maturation of T cells

The T cell life begins as a hematopoietic stem cell (HSC) in the bone marrow. The HSCs leave the bone marrow, circulate in the blood and enter the thymus as thymus-settling progenitors (TSPs) <sup>13-15</sup>. The development of CD4<sup>+</sup> or CD8<sup>+</sup> T cells depends on the microenvironment of the thymus, at which each of the four major thymic compartments (subcapsular zone, cortex, medulla, corticomedullary junction) is involved in a specific stage of the thymocyte development <sup>16-21</sup>. The T cell development in the thymus is a tightly controlled cascade of separate developmental steps <sup>14,20</sup>. The most important cell-surface markers, which allow the identification of different developmental stages of thymocytes, are CD4, CD8, CD25, CD44 and CD117. The expression of these markers remains within the rearrangement steps of the T cell receptor (TCR) chains. <sup>14,19</sup> After tiny numbers of TSPs enter the thymus, they go through four CD4/CD8 double-negative (DN) stages (DN1-DN4) <sup>14,19,20,22</sup>. The earliest DN cells, DN1 express high levels of CD117 as well as CD44 but are negative for CD25 <sup>14</sup>. The DN1 cells are first detectable in the corticomedullary junction (CMJ) of the thymus, where they undergo proliferation <sup>14,16-19</sup>. Furthermore, via Notch1 signalling the DN1 cells become a more T cell-restricted progenitor and less multipotent, a process called T cell lineage commitment <sup>14,19</sup>. The DN1 thymocytes migrate to the subcapsular zone (SCZ), deeper in the cortex <sup>14,16,17</sup>. Stimulatory signals from cortical thymic epithelial cells (cTECs) and fibroblasts induce the differentiation into DN2 cells (CD25<sup>+</sup>CD44<sup>+</sup>CD117<sup>int</sup>) <sup>14,20</sup>. The DN2 thymocytes further proceed in T cell lineage commitment <sup>14,20</sup>. Furthermore, this step is characterised by the TCR  $\beta$ -chain rearrangement <sup>14,20</sup>. This process is also called  $\beta$ -selection and is finished in the DN3 stage <sup>14,20</sup>. The DN3 (CD25<sup>+</sup>CD44<sup>lo</sup>CD117<sup>lo</sup>) thymocytes are still present within

the SCZ and mature to DN4 cell (CD25<sup>-</sup>CD44<sup>-</sup>CD117<sup>-</sup>)<sup>14,16,17,20</sup>. During the migration back to the thymic medulla, DN4 thymocytes up-regulate CD4 and CD8 after successful pre-TCR signalling within the outer cortex<sup>14,16,17,20</sup>. In these double-positive (DP) thymocytes the rearrangement of the TCR  $\alpha$ -chain occurs<sup>14,23</sup>. Furthermore, in the DP stage the developing T cells undergo a process called positive selection<sup>14,20,23</sup>. During this process, DP thymocytes recognising self-peptides presented by MHC-complexes of cTECs, DCs and fibroblasts<sup>14,20,23</sup>. Those DP cells which recognise self-peptides with low affinity survive and further differentiate into single-positive (SP) thymocytes, either expressing CD4 or CD8<sup>14,20,23-25</sup>. Additionally, those thymocytes with a low affinity to self-peptides are protected from neglect and switch off further TCR  $\alpha$ -chain gene rearrangement<sup>23</sup>. The newly formed SP thymocytes migrate into the thymic medulla<sup>14,20</sup>. The medulla is the place for negative selection, eliminating SP cells with a high affinity to self-peptides presented by medullary TECs (mTECs)<sup>14,20,22-25</sup>. Consequently, negative selection is an process to eliminate autoreactive T cells<sup>14,20,22-25</sup>.

**Figure 1: Thymic migration of maturing T cells:** Hematopoietic stem cells (HSC) leave the bone marrow, circulate in blood and enter the thymus as thymus-settling progenitors (TSPs) at the corticomedullary junction (CMJ). TSPs run through four CD4/CD8 double-negative (DN) maturation stages. Via Notch-signalling DN1 cells ( $CD25^+CD44^+CD117^{hi}$ ) start to become more committed to the T cell lineage. DN1 cells migrate to the subcapsular zone (SCZ) and mature to DN2 cells upon stimulation by thymic epithelial cells (cTECs). In DN2 cells ( $CD25^+CD44^+CD117^{int}$ ) the  $\beta$ -selection starts and is completed in DN3 cells ( $CD25^+CD44^{lo}CD117^{lo}$ ). The DN3 cells mature to DN4 cells ( $CD25^-CD44^-CD117^-$ ), which start to migrate back to thymic medulla. Within the outer cortex DN4 cells become double-positive (DP) for CD4 and CD8. Within DP cells the rearrangement of the TCR  $\alpha$ -chain occurs. Self-antigens presented by cTECs induce the positive selection of DN cells, which afterwards mature to single-positive (SP) cells. The negative selection of SP cells takes place within the medulla and eliminates highly autoreactive cells. The newly formed  $CD4^+$  and  $CD8^+$  T cells exit the thymus.

### 1.3 T helper cell differentiation

The presence of two distinct  $CD4^+$  T cell subsets was first described by Mosmann *et al.* showing a unique cytokine expression by these T cells<sup>26</sup>. Hence, Mosmann *et al.* named them T helper 1 and T helper 2 ( $T_H1$  and  $T_H2$ ) cells according to their cytokine production<sup>26</sup>. A further peripheral  $T_H$  cell subset was discovered recently and named  $T_H17$

cells<sup>27–33</sup>. These three major T<sub>H</sub> cell types are distinguishable by their unique cytokine production and their function<sup>28,30,31,34,35</sup>. The T<sub>H</sub>1 cells, which predominantly express interferon- $\gamma$  (IFN  $\gamma$ ) are essential in protecting the host against intracellular viruses and bacteria<sup>28,30,31,34</sup>. T<sub>H</sub>2 cells on the other hand, are important for the defence against extracellular pathogens (e.g. helminths) and produce interleukin 4 (IL4), IL5, IL9, IL13 and IL25<sup>28,30,31,34</sup>. T<sub>H</sub>17 cells are characterised by the production of IL17A, IL17F as well as IL22 and control extracellular bacteria and fungi<sup>27–31,34</sup>. Next to their immune-protective function, both T<sub>H</sub>1 and T<sub>H</sub>17 cells are implicated in autoimmune diseases and T<sub>H</sub>2 cells are involved in allergic responses<sup>35,36</sup>. The fourth T cell subset, known as regulatory T (Treg) cells can either differentiate from peripheral naïve CD4<sup>+</sup> T cells (induced Treg; iTreg), as the other T<sub>H</sub> cells or develop in the thymus (thymic derived Treg; tTreg)<sup>28,30,31,37–39</sup>. In contrast to other T<sub>H</sub> cells, which promote immune responses, Treg cells are immune suppressive<sup>28,30,31,37–39</sup>.

After triggering of the TCR, the differentiation of T<sub>H</sub> cells is directed by several T<sub>H</sub> cell subset specific requirements. Firstly, the surrounding cytokine milieu at the time of TCR stimulation plays a critical role in determining the T<sub>H</sub> cell commitment<sup>28–31</sup>. A unique combination of cytokines is required for the differentiation of a specific T<sub>H</sub> cell lineage (Figure 2)<sup>28–31</sup>. Secondly, members of the signal transducer and activator of transcription (STAT) family and master transcription factors collaborate in T cell differentiation and expansion (Figure 2)<sup>29,31</sup>. Thirdly, the T<sub>H</sub> cell commitment is additionally supported by one of the effector cytokines of the particular T<sub>H</sub> cell subset, thereby providing a powerful positive feedback loop (Figure 2)<sup>29,31</sup>. Finally, cytokines of the IL1 family are suggested to induce the effector cytokine production together with STAT activators in a TCR-independent manner (IL18 for Th1, IL33 for Th2 and IL1 for Th17 cells)<sup>31</sup>. Consequently, the commitment of T cell subsets takes place, they selectively mature and the master regulator of the committed T cell actively suppress an alternative lineage fate<sup>29,31</sup>. For instance, IFN $\gamma$  and IL27 activate STAT1, which initiates the development of T<sub>H</sub>1 cells<sup>29,31</sup>. The master transcription factor of T<sub>H</sub>1 cells, Tbet is induced by STAT1 together with TCR-activated transcription factors and Tbet in turn initiates the production of IFN $\gamma$ <sup>29,31</sup>. Furthermore, IL12 secreted by APCs activates STAT4, which induce together with Tbet induces the expression of IFN $\gamma$  within T<sub>H</sub>1 cells. Hence, via a positive-feedback loop IFN $\gamma$  intensifies the T<sub>H</sub>1 cell commitment by further activation of STAT1 (Figure 2)<sup>29,31</sup>.

**Figure 2: T helper cell differentiation.** Upon the TCR activation triggered by antigen-presenting cells (e.g. DCs) a naïve  $CD4^+$  T cell can differentiate into four subsets, namely,  $T_H1$ ,  $T_H2$ ,  $T_H17$  or Treg cell. Each T cell differentiation depends on a critical combination of cytokines: IL12 and  $IFN\gamma$  for  $T_H1$ , IL4 and IL2 for  $T_H2$ ,  $TGF\beta$  and IL6 (IL21/IL23) for  $T_H17$ , and  $TGF\beta$  and IL2 for iTreg cells. The lineage commitment involves the up-regulation of lineage characteristic master transcription factors (highlighted in orange) and the activation of STAT proteins (highlighted in yellow). Each committed  $T_H$  cell expresses a unique combination of effector cytokines (highlighted in blue), and one of these cytokines promotes further lineage commitment (written in blue). In addition, committed T cells express receptors directed to IL1 cytokine family members (red-rimmed), which induce an effector cytokine expression in a TCR-independent way.

#### 1.4 The differentiation of $T_H17$ cells

The differentiation of  $T_H17$  cells (Figure 2) is a subject of ongoing research and further investigations are necessary to decrypt the exact mechanism<sup>29–31,34</sup>.  $T_H17$  cell differentiation is independent of cytokines and transcription factors, which are important in  $T_H1$  and  $T_H2$  development<sup>33,40–42</sup>.  $IFN\gamma$  and IL4 are essential cytokines in  $T_H1$  or  $T_H2$  differentiation, but inhibit the development to IL17 producing T cells<sup>33,40,42</sup>. Furthermore, the cytokine IL2, which is required for  $T_H2$  and Treg cell development and clonal expansion, blocks  $T_H17$  cells by the activation of STAT5<sup>41,43,44</sup>. During  $T_H17$  cell differentiation the secretion of IL2 is suppressed by binding of Aiolos, a member of the Ikaros transcription factor family, to the *Il2* locus<sup>41</sup>.

The member of the STAT family STAT3 and the retinoic-acid-receptor-related orphan receptor- $\gamma$ t (ROR $\gamma$ t) are essential proteins in T<sub>H</sub>17 cell differentiation (Figure 2) <sup>45–47</sup>. ROR $\gamma$ t is the master transcription factor of T<sub>H</sub>17 cells <sup>48–51</sup>. The necessity of ROR $\gamma$ t in T<sub>H</sub>17 cell formation was detected by analysing mice deficient for ROR $\gamma$ t, which showed a reduced development of IL17 expressing cells <sup>46,49,52</sup>. Furthermore, the disruption of STAT3 in mice resulted in the absence of T<sub>H</sub>17 cells <sup>46,52,53</sup>. Fork-head box P3 (Foxp3), the master transcription factor of Treg cells, inhibits the master transcription factor of T<sub>H</sub>17 cells, ROR $\gamma$ t, by direct binding and, thus, blocks the T<sub>H</sub>17 cell differentiation <sup>29</sup>. Both the transforming growth factor  $\beta$  (TGF $\beta$ ) and IL6 are essential to promote the T<sub>H</sub>17 cell differentiation at the time of TCR activation <sup>40,54–56</sup>. While TGF $\beta$  inhibits the differentiation of T<sub>H</sub>1 and T<sub>H</sub>2 cells, it promotes Treg and T<sub>H</sub>17 cell development by the induction of the transcription factors Foxp3 and ROR $\gamma$ t <sup>29,40,42,54,55,57,58</sup>. The level of TGF $\beta$  is one pivotal factor of the T<sub>H</sub>17 or Treg fate decision <sup>59</sup>. The induction of Foxp3 for Treg development requires high concentrations of TGF $\beta$  <sup>59</sup>, while a low level of TGF $\beta$  promote T<sub>H</sub>17 cell differentiation <sup>59</sup>. In contrast to TGF $\beta$ , IL6 induces the development of T<sub>H</sub>17 cells, while inhibiting Treg cell development <sup>46,52,55,59,60</sup>. Thus, the presence of TGF $\beta$  together with IL6 induces T<sub>H</sub>17 cell development by the activation of STAT3 <sup>46,52,61</sup>. STAT3 itself leads to the induction of ROR $\gamma$ t expression <sup>45,46</sup>. Subsequently, additionally to its ability to support ROR $\gamma$ t expression <sup>45,46</sup> STAT3 inhibits the expression of Foxp3 and its interaction with ROR $\gamma$ t <sup>45,55,62</sup>. The increased availability of ROR $\gamma$ t enhances the commitment of the T<sub>H</sub>17 lineage fate <sup>46,48,50,59</sup>. Furthermore, upon the initiation of T<sub>H</sub>17 differentiation STAT3 together with IL6 induce the expression of IL21 and the IL23 receptor (IL23R) <sup>46,53,61,63</sup>. The three cytokines IL6, IL21 and IL23 are activators of STAT3 <sup>45,46,60,63</sup>. Thus, a positive-feedback loop leads to exacerbated STAT3 expression via endogenous IL21 as well as APC-derived IL6 and IL23 <sup>45,46,60,63</sup>. Due to the lack of IL23R on naïve CD4<sup>+</sup> T cells, IL23 is not essential for T<sub>H</sub>17 cell differentiation but for their survival and expansion <sup>30,45,56</sup>. Furthermore, IL21 and IL23 promote the expansion of T<sub>H</sub>17 cells and finalize T<sub>H</sub>17 cell development <sup>55,56</sup>. The expression of the effector cytokine of T<sub>H</sub>17 cells, IL17A is induced by ROR $\gamma$ t and STAT3 <sup>46,48,49,51</sup>. Furthermore, ROR $\gamma$ t synergistically regulates the IL17A expression together with runt-related transcription factor 1 (Runx1) <sup>48</sup>. The optimal expression of ROR $\gamma$ t is induced by Runx1, both bind to the *Il17* locus and induce the expression of IL17A and IL17F <sup>48</sup>.

Recently the participation of IL1 $\beta$  to the T<sub>H</sub>17 differentiation was identified<sup>44,56,64–67</sup>. Mice deficient for IL1 $\beta$  or its receptor failed to generate a robust T<sub>H</sub>17 cell response in infections (e.g. *Candida albicans*)<sup>64,66</sup>. Furthermore, IL1R-deficient mice are less susceptible to experimental autoimmune encephalomyelitis (EAE) induction, since T<sub>H</sub>17 cells in contrast to T<sub>H</sub>1 and T<sub>H</sub>2 cells were defective to become autoreactive in these mice<sup>68</sup>. Moreover, IL1 $\beta$  acts together with TNF $\alpha$  and synergizes with IL6 and IL23 to promote the induction as well as the amplification of the T<sub>H</sub>17 cell commitment<sup>44,56,64–67</sup>. IL1 $\beta$  may support T<sub>H</sub>17 cell differentiation due to its ability to antagonise the effects of IL2<sup>44</sup> and IL12<sup>66</sup>. In addition, IL1 $\beta$  contributes to T<sub>H</sub>17 cell differentiation by induction of the transcription factor IRF4 (IRF4)<sup>67</sup>, which is involved in IL21-mediated T<sub>H</sub>17 cell development<sup>63,69</sup>.

### 1.5 T<sub>H</sub>17 cells, a pro-inflammatory T cell subset in health and disease

T<sub>H</sub>17 cells can be found throughout the body and most of them are present in the lung and intestinal tract<sup>44</sup>. An incomplete matured immune response as well as the absence of T<sub>H</sub>17 cells were found in adult mice that grow up in a germ-free environment as well as in neonates<sup>4,5,70</sup>. It was shown, that gut dendritic cells from germ-free mice were reduced in their ability to induce proinflammatory T cells<sup>5</sup>. Within days, a robust T<sub>H</sub>17 cell compartment is induced by the administration of commensal microorganisms to germ-free mice<sup>70</sup>. Especially the gut colonising segmented filamentous bacteria (SFB) were able to promote the T<sub>H</sub>17 cell differentiation<sup>5,7,71,72</sup>. The intestinal microorganisms induced the expression of IL1 by intestinal macrophages, which in turn initiated T<sub>H</sub>17 cell development<sup>65</sup>. Hence, the composition of the gut microflora regulates the T<sub>H</sub>17 cell differentiation<sup>5,7,65,70–72</sup>. On the other hand, T<sub>H</sub>17-derived cytokines such as IL17 and IL22 contribute to the regulation of the commensal gut microflora<sup>2</sup>. Furthermore, host protection to extracellular pathogens could be linked to T<sub>H</sub>17 cells and their effector cytokines<sup>73</sup>. For instance, IL17 activates epithelial cells to produce anti-microbial peptides and monocyte-recruiting chemokines<sup>73,74</sup>. Parenchymal cells are initiated by IL17 to release inflammation mediators like cytokines and chemokines<sup>73,74</sup>. In addition, IL17R-signaling promotes the generation, attraction and activation of neutrophils and monocytes to clear infection by phagocytosis<sup>73,74</sup>. Secreted IL22 induces the proliferation of epithelial cells for repairing invasion-induced damage and promotes the expression of anti-microbial peptides<sup>73</sup>. T<sub>H</sub>17 cells are necessary to promote the defence against a immense diversity of

pathogens e.g. *Candida albicans*, *Citrobacter rodentium*, *Klebsiella pneumoniae*, *Salmonella typhimurium* and *Staphylococcus aureus*<sup>66,73,75–78</sup>.

First T<sub>H</sub>1 cells were thought to be the inducers of autoimmunity, but since the discovery of IL17 secreting cells, numerous autoimmune diseases were shown to depend partially or mainly on a T<sub>H</sub>17 cell immune responses<sup>7,36,73,75,79–84</sup>. A crucial role of IL23 rather than the T<sub>H</sub>1 cytokine IL12 was suggested in EAE, arthritis, inflammatory bowel disease and psoriasis<sup>73–75,85,86</sup>. Furthermore, *in vivo* studies indicate that the protective immune response of T<sub>H</sub>17 cells as well as their autoimmunity depend on IL23 rather than IL6 and TGFβ<sup>40,85</sup>. For instance, in *Citrobacter rodentium* infection the T<sub>H</sub>17 differentiation depend on TGFβ and IL6 but not IL23<sup>40</sup>. However, IL23 is essential in host protection, since IL23-deficient mice are more susceptible to *Citrobacter rodentium* infection compared to wildtype mice<sup>40</sup>. The disruption of the myelin in the central nervous system during multiple sclerosis and the corresponding mouse model, EAE depends on autoreactive T<sub>H</sub>1 and T<sub>H</sub>17 cells<sup>82–84</sup>. Similar to *Citrobacter rodentium* infection, studies of EAE suggest that the pathogenic function of T<sub>H</sub>17 cells depends on IL23 rather on IL6 and TGFβ<sup>85</sup>. Myelin-autoreactive T cells, stimulated with IL6 and TGFβ, were present in the central nervous system of immunised mice, but were not able to induce demyelination<sup>85</sup>. On the contrary, myelin-specific T cells stimulated with IL23 established inflammation of the central nervous system<sup>85</sup>. IL6 and TGFβ stimulated T cell produced anti-inflammatory IL10 in contrast to IL23 stimulated cells, which was suggested to reduce the anti-inflammatory function of the myelin-specific T<sub>H</sub>17 cells<sup>85</sup>. Additionally, mice deficient for IL23 are protected from EAE, supporting the essential role of IL23 in autoimmunity<sup>86</sup>. A similar pattern of resistance to autoimmunity was identified in mice deficient for granulocyte-macrophage colony-stimulating factor (GM-CSF)<sup>87,88</sup>. The studies on GM-CSF showed that IL23 together with RORγt direct the expression of GM-CSF in T<sub>H</sub>17 cells and by a positive feedback loop GM-CSF of T<sub>H</sub>17 cells activates APCs to produce IL23<sup>87,88</sup>. T<sub>H</sub>17-secreated GM-CSF itself sustained the neuroinflammations in EAE, because it activate myeloid cells to infiltrate the central nervous system<sup>87,88</sup>. Thus, the manipulation of the T<sub>H</sub>17 lineage commitment may provide new opportunities for the enhancement of mucosal immunity and the treatment of autoimmune diseases.

## 1.6 The transcription factor nuclear factor (NF)- $\kappa$ B

In 1986 the nuclear factor- $\kappa$ B (NF- $\kappa$ B) was first described by Sen and Baltimore as a transcription factor interacting with the immunoglobulin  $\kappa$  light chain enhancer in B cells<sup>89</sup>. Since then it has been shown that NF- $\kappa$ B is a key mediator of inducible gene expression in a wide range of cellular processes<sup>90–94</sup>. The NF- $\kappa$ B network is a global mechanism regulating cell survival and differentiation as well as the interaction between cells<sup>90–94</sup>. NF- $\kappa$ B is crucial in the immune system for both innate and adaptive immune responses<sup>93,95</sup>. For instance, NF- $\kappa$ B regulates lymphocyte survival, development and activation<sup>93,95–97</sup>. Moreover, it is essential in the formation of tissues important for lymphocyte development and activation<sup>93,95–97</sup>.

The mammalian NF- $\kappa$ B (also named Rel) protein family (Figure 3) includes the five members p50/p105 (NF- $\kappa$ B1), p52/p100 (NF- $\kappa$ B2), p65 (RelA), cRel and RelB<sup>92,96,98</sup>. Both p105 and p100 are precursors and the two Rel proteins p50 and p52 are generated by post-translational cleavage for later dimerisation<sup>94,95,98</sup>. All members exhibit an N-terminal Rel-homology domain (RHD) including a nuclear localisation signal (NLS), a DNA-binding motif and a dimerisation domain<sup>92,96,98</sup>. Via the latter domain, two NF- $\kappa$ B proteins form a dimer and the DNA-binding motif allows the binding of the dimer to  $\kappa$ B sites on the DNA<sup>92,96,98</sup>. Moreover, the Rel family members p65, cRel and RelB have a transcription activation domain (TAD), which is essential for the binding of co-activators<sup>96,98</sup>. NF- $\kappa$ B dimers containing at least one TAD can induce the transcription of the target gene<sup>96,98</sup>. The TAD is missing in p50 and p52, so that these two Rel proteins are only transcriptionally active when forming heterodimers with p65, cRel or RelB<sup>96,98</sup>. When bound to  $\kappa$ B sites on the DNA, homodimers of p50 or p52 repress the transcription of the corresponding gene<sup>96,99</sup>.

**Figure 3: The members of the NF- $\kappa$ B family:** The five members of the NF- $\kappa$ B/ Rel protein family p50/p105 (NF- $\kappa$ B1), p52/p100 (NF- $\kappa$ B2), p65 (RelA), cRel and RelB are illustrated. The post-translational cleavage of the precursor proteins p105 and p100 leads to the generation of the two proteins p50 and p52 (cleavage sites are marked with an arrow). The N-terminal Rel-homology domain (RHD) includes a nuclear localisation signal (NLS), a DNA-binding motif and a dimerisation domain. The Rel family members p65, cRel and RelB have a transcription activation domain (TAD).

### 1.7 The I $\kappa$ B protein family - regulators of NF- $\kappa$ B

The activity of NF- $\kappa$ B is regulated by the inhibitors of NF- $\kappa$ B (I $\kappa$ Bs) protein family. The classical function of the I $\kappa$ B family members (Figure 4) is to retain NF- $\kappa$ B dimers in the cytoplasm by masking their NLS and thereby inhibiting its transcriptional function<sup>95,99–102</sup>. Over the years of extensive research, it became apparent that the I $\kappa$ B family is a functionally heterogeneous group of NF- $\kappa$ B regulators, which can either inhibit or enhance its activity<sup>99,100,102</sup>.

The common structural motif of all I $\kappa$ Bs is the ankyrin repeat domain (ARD) containing six to eight single ankyrin repeats<sup>92,93,96,100,102–104</sup>. Each ankyrin repeat comprises 33 amino acids folded into a helix-loop-helix conformation<sup>100,103</sup>. The ARD is essential for the protein stability and the interaction with the RHDs of NF- $\kappa$ B dimers<sup>100,101</sup>. Furthermore, classical I $\kappa$ Bs exhibit an unfolded structure N-terminal of the ARD with a signal response domain (also called degron motif), containing serine residues for stimulation-dependent phosphorylation by IKK<sup>100</sup>. In addition, the polyubiquitination of typical I $\kappa$ B proteins occurs at lysine residues, located upstream of the phosphorylation sites<sup>100</sup>. Two of the typical I $\kappa$ Bs have a region called PEST (rich in proline, glutamic acid, serine and

threonine), which is suggested to mediate fast protein turnover<sup>100</sup>. The NF- $\kappa$ B family members p100 and p105 contain C-terminal NF- $\kappa$ B-inhibiting ankyrin repeats as well as an N-terminal Rel homology domain. Hence, they belong to both the Rel and the I $\kappa$ B protein family<sup>91,100</sup>.

The I $\kappa$ B protein family is divided into two groups the classical I $\kappa$ Bs (I $\kappa$ B $\alpha$ , I $\kappa$ B $\beta$ , I $\kappa$ B $\epsilon$ ) and the atypical I $\kappa$ Bs (Bcl3, I $\kappa$ B $\zeta$ , I $\kappa$ B<sub>NS</sub>, I $\kappa$ B $\eta$ , I $\kappa$ BL) (Figure 4)<sup>91,100–102</sup>. In contrast to the mainly cytoplasmic classical I $\kappa$ Bs, the atypical I $\kappa$ Bs are predominantly located in the nucleus<sup>91,100–102</sup>. The cytoplasmic I $\kappa$ Bs primarily inhibit basal NF- $\kappa$ B activity in unstimulated cells and are degraded upon stimulation to release NF- $\kappa$ B dimers for rapid transcriptional activity<sup>91,100</sup>. Atypical I $\kappa$ Bs on the other hand have a low expression level in resting cells, which drastically increase upon cell stimulation<sup>91,100,102</sup>. Furthermore, nuclear I $\kappa$ Bs can act as inhibitors or enhancers of NF- $\kappa$ B and thereby provide a fine-tuning mechanism for transcriptional responses<sup>91,100,102</sup>. The atypical I $\kappa$ B protein Bcl3 was first identified as a protooncogene in chronic lymphatic leukaemia<sup>105</sup>. Later it was reported that Bcl3 is important to promote B cell proliferation and development, germinal centre formation, humoral immune responses as well as formation of antigen-specific antibodies<sup>106,107</sup>. In stimulated macrophages, Bcl3 is detectable in the nucleus and inhibits lipopolysaccharide-induced (LPS-induced) TNF $\alpha$  production, but not IL6<sup>108</sup>. It is known that Bcl3 preferentially associates with p50 and p52 homodimers<sup>109–112</sup> and thereby either activates or inhibits their function<sup>111–114</sup>. The activation of p50 homodimers is mediated by the transcription activation domain (TAD) of Bcl3<sup>113</sup>. Next to Bcl3, the only I $\kappa$ B protein with a TAD is the nuclear I $\kappa$ B $\zeta$  (also called MAIL), which mediates a gene-specific recruitment of NF- $\kappa$ B to its target promoter<sup>115,116</sup>. Furthermore, I $\kappa$ B $\zeta$  negatively regulates the activity of p65/p50 heterodimers and p50/p50 homodimers<sup>117,118</sup>. I $\kappa$ B $\zeta$  is induced by cell stimulation with LPS and IL1 $\beta$ , but not TNF $\alpha$ <sup>118,119</sup> and seems to be important for the regulation of apoptosis<sup>118,120</sup>. Furthermore, IL6 and IL12p40 are regulated by I $\kappa$ B $\zeta$ <sup>119</sup>. The development of T<sub>H</sub>17 cells depends on I $\kappa$ B $\zeta$ , shown in I $\kappa$ B $\zeta$ -deficient mice exhibiting a defect in T<sub>H</sub>17 proliferation and resistance to EAE induction<sup>121</sup>. Additionally, I $\kappa$ B $\zeta$  cooperates with ROR $\gamma$ t and ROR $\alpha$  to bind to the IL17A gene and induces its expression<sup>121</sup>. I $\kappa$ B $\eta$ <sup>122</sup> and I $\kappa$ BL<sup>123,124</sup> are two recently identified atypical I $\kappa$ B proteins. The expression of I $\kappa$ B $\eta$  is stimulation-dependent (e.g. LPS), as it was shown for atypical I $\kappa$ Bs<sup>122</sup>. I $\kappa$ B $\eta$  associates with p50 NF- $\kappa$ B subunits and regulates the expression of

proinflammatory cytokines such as IL6 and IL1 $\beta$ <sup>122</sup>. I $\kappa$ BL prevents the development of experimental autoimmune arthritis and is suggested to suppress the LPS-induced NF- $\kappa$ B activation and transcription of TNF $\alpha$  and IL6, but not IL1 $\beta$ <sup>123,124</sup>.

**Figure 4: The pleiotropic I $\kappa$ B protein family:** The I $\kappa$ B family is divided into the cytoplasmic (I $\kappa$ B $\alpha$ , I $\kappa$ B $\beta$ , I $\kappa$ B $\epsilon$ , p100, p105) and the atypical nuclear I $\kappa$ Bs (Bcl3, I $\kappa$ B $\zeta$ , I $\kappa$ B $\text{NS}$ , I $\kappa$ B $\eta$ , I $\kappa$ BL). All members contain ankyrin repeats (ANK). Bcl3 and I $\kappa$ B $\zeta$  exhibit a transcription activation domain (TAD). The proteins p100 and p105 have both ankyrin repeats as well as Rel-homology domain (RHD). Consequently, they are grouped into both Rel and I $\kappa$ B protein families.

## 1.8 The cytoplasmic regulation of NF- $\kappa$ B by I $\kappa$ Bs

In unstimulated cells, NF- $\kappa$ B dimers are inactivated via binding to cytoplasmic I $\kappa$ Bs, which mask the NLS of the Rel protein (Figure 5)<sup>93,99,125</sup>. Several cell-activating signals can initiate the NF- $\kappa$ B pathway. These signals range from pro-inflammatory cytokines (e.g. TNF, IL1, IL17), cell stress (e.g. reactive oxygen species, DNA double-strand breaks)

and PAMPs (e.g. nucleic acids, peptides, lipoprotein) to TCR or BCR engagement<sup>96</sup>. Upon cell activation, the NF- $\kappa$ B-bound I $\kappa$ B $\alpha$  becomes phosphorylated at the two serine residues 32 and 36<sup>98,103,126</sup>. This phosphorylation is conducted by the I $\kappa$ B kinase (IKK) complex, which consists of the regulatory subunits IKK $\gamma$  (NEMO) and two catalytic units IKK $\alpha$  and IKK $\beta$ <sup>95,99,101,126</sup>. The phosphorylation of I $\kappa$ B $\alpha$  induces polyubiquitination and its proteasomal degradation<sup>95,99,101,126</sup>. This allows the translocation of the functionally active NF- $\kappa$ B into the nucleus where it binds to its cognate  $\kappa$ B-binding motif on the DNA and induces gene expression<sup>93,99,103,104</sup>. One target of NF- $\kappa$ B is its own inhibitor I $\kappa$ B $\alpha$ , the prototypical member of the I $\kappa$ B family, and the intracellular level of I $\kappa$ B $\alpha$  is refilled upon gene induction by NF- $\kappa$ B<sup>100,103</sup>. Subsequently, I $\kappa$ B $\alpha$  mediates, via its nucleocytoplasmic-shuttling properties, the translocation of NF- $\kappa$ B back to the cytoplasm and thereby contributes to the termination of the NF- $\kappa$ B-induced gene transcription in a negative feedback loop<sup>99,100,103</sup>. Beside the I $\kappa$ B proteins, several mechanisms essential for the termination of transcription and the displacement of NF- $\kappa$ B from the DNA have been described<sup>99</sup>. This includes the altered binding of co-factors, the degradation of NF- $\kappa$ B after ubiquitination, and the displacement of NF- $\kappa$ B dimers from the DNA by small ubiquitin-like modifiers (SUMOylation)<sup>99</sup>.

In addition to the canonical or classical pathway, which is outlined above, there exists a second NF- $\kappa$ B pathway<sup>12,91,101,103,104,126</sup>. This non-canonical or alternative Rel pathway is induced by the tumour necrosis factor (TNF) cytokine family including CD40 ligands, BAFF and lymphotoxin B<sup>91</sup>. In contrast to the canonical pathway, the non-canonical NF- $\kappa$ B pathway is independent of IKK $\gamma$ , but depends on IKK $\alpha$ <sup>91,103,104</sup>. In canonical NF- $\kappa$ B signalling, TRAF/RIP complexes process and transfer the activation signals to IKK<sup>91,103,104</sup>. On the contrary, the non-canonical pathway depends on the NF- $\kappa$ B inducing kinase (NIK), which phosphorylates and activates IKK $\alpha$ <sup>91,101,103,104</sup>. The activation of IKK $\alpha$  causes the phosphorylation of p100 followed by a proteasomal processing of p100 to p52<sup>91,101,103,104</sup>. The p100 is processed until a glycine rich region (GRR), which serves as proteasomal termination signal<sup>101</sup>. Subsequently, the generated p52/RelB heterodimers translocate into the nucleus, bind to  $\kappa$ B sites and initiate the expression of the corresponding gene<sup>91,101,103,104</sup>.

**Figure 5: The canonical NF- $\kappa$ B pathway:** Two NF- $\kappa$ B subunit proteins form a dimer, which is sequestered into the cytoplasm by binding to inhibitors of NF- $\kappa$ B proteins (I $\kappa$ Bs). The I $\kappa$ B kinase complex (IKK), consisting of IKK $\alpha$ , IKK $\beta$  and IKK $\gamma$  becomes activated upon cell stimulation. The IKK phosphorylates the I $\kappa$ B protein at the serine residues 32/36 and is followed by polyubiquitination and proteasomal degradation of I $\kappa$ B. Then the released NF- $\kappa$ B dimer translocate into the nucleus, binds to specific  $\kappa$ B-sites and induces gene expression.

### 1.9 I $\kappa$ B<sub>NS</sub> - the novel regulator of NF- $\kappa$ B

The product of the NF $\kappa$ B gene I $\kappa$ B<sub>NS</sub> is also known as T cell activation NF- $\kappa$ B-like protein (TA-NFKBH). It is the smallest member of the nuclear I $\kappa$ B protein family and consists of 327 amino acids<sup>127</sup>. Fiorini *et al.* showed the TCR-induced expression of I $\kappa$ B<sub>NS</sub> in thymocytes for the first time in 2002<sup>127</sup>. Beside the TCR-triggered induction of I $\kappa$ B<sub>NS</sub><sup>127,128</sup>, it is now known that the expression of I $\kappa$ B<sub>NS</sub> as well as Bcl3 is also inducible by IL10<sup>108,129</sup>. Furthermore, upon IL10 production an elevated expression of I $\kappa$ B<sub>NS</sub> and Bcl3 was observed in LPS triggered regulatory DCs, which express less proinflammatory cytokines and instead preferentially IL10 compared to usual DCs<sup>130</sup>. Fiorini and colleagues identified that I $\kappa$ B<sub>NS</sub> transcription was activated by peptides triggering negative but not positive selection<sup>127</sup>. Thus, it was first suggested that I $\kappa$ B<sub>NS</sub> might play an important role in central tolerance. Interestingly, the transcription of NF- $\kappa$ B reporter proteins was blocked by I $\kappa$ B<sub>NS</sub>. In addition, the interaction of I $\kappa$ B<sub>NS</sub> with NF- $\kappa$ B was observed within the nucleus<sup>127</sup>.

In contrast to the suggested central role of I $\kappa$ B<sub>NS</sub> in negative selection in the thymus, I $\kappa$ B<sub>NS</sub>-deficient mice did not develop autoimmune diseases and no changes in thymocytes or T cell subsets were detectable<sup>128,131</sup>. However, B cells from I $\kappa$ B<sub>NS</sub>-deficient animals were defective in their proliferation upon LPS stimulation<sup>132,133</sup>. In addition to the proliferation defect of I $\kappa$ B<sub>NS</sub>-deficient B cells, the serum IgM and IgG3 were drastically reduced upon the loss of I $\kappa$ B<sub>NS</sub><sup>132,133</sup>. Furthermore, the defect of I $\kappa$ B<sub>NS</sub> induced a reduction of antibody-producing cells and diminished levels of influenza-specific antibodies were detected upon infection<sup>132</sup>. Additionally, I $\kappa$ B<sub>NS</sub>-deficient T cells revealed a proliferation defect upon LPS stimulation<sup>128,132</sup> and are highly susceptible to LPS induced endotoxin shock as well as intestinal inflammation<sup>131</sup>. Furthermore, the LPS-triggered expression of IL6 and IL12p40, but not TNF $\alpha$  is increased in macrophages lacking I $\kappa$ B<sub>NS</sub><sup>129,131</sup>. The IL6 expression is regulated by I $\kappa$ B<sub>NS</sub> by its association with p50. Both proteins are recruited to the IL6 promoter and inhibit as well as terminate the binding of p65<sup>129,131</sup>. In contrast to the inhibitory effect of I $\kappa$ B<sub>NS</sub> on the IL6 production, it is dispensable for the expression of TNF $\alpha$ <sup>129,131</sup>. It has been reported that cRel and I $\kappa$ B $\zeta$  regulate the activity of NF- $\kappa$ B in an opposite manner compared to I $\kappa$ B<sub>NS</sub>. For instance, in contrast to I $\kappa$ B<sub>NS</sub>, Bcl3 inhibits the expression of TNF $\alpha$  by its cooperative binding with p50 to the TNF $\alpha$  promoter<sup>108</sup>. Furthermore, while I $\kappa$ B<sub>NS</sub> inhibits the expression of IL6, Bcl3 is dispensable for the its expression<sup>108</sup> and I $\kappa$ B $\zeta$  enhance the IL6 production<sup>119</sup>. I $\kappa$ B $\zeta$  regulates this induction by its association with p50 (presumably p50 of p50/RelA heterodimers). Both are recruited to the IL6 promoter and support the IL6 expression<sup>119</sup>. In addition, I $\kappa$ B<sub>NS</sub> is important for the expression of IL2 and IFN $\gamma$  in thymocytes and T cells<sup>128</sup>. I $\kappa$ B<sub>NS</sub> enhances the expression of IL2 via the association to its promoter, presumably by the interaction to cRel or p50, but also other still unknown DNA-binding proteins are suggested<sup>128</sup>. Since I $\kappa$ B<sub>NS</sub> itself has no DNA binding domain, it needs to cooperate with DNA-binding proteins to bind to promoters<sup>128</sup>.

Interestingly, a recent report on I $\kappa$ B<sub>NS</sub> revealed its function for Treg cell development<sup>134</sup>. I $\kappa$ B<sub>NS</sub>-deficient mice showed a significant reduction of mature Treg cells, although Treg precursor cells (GITR<sup>+</sup>CD25<sup>+</sup>Foxp3<sup>-</sup>) accumulated in the thymus. Furthermore, a transient expression of I $\kappa$ B<sub>NS</sub> during thymic Treg development was observed. It was shown that I $\kappa$ B<sub>NS</sub> is essential for the transition of immature thymic Treg precursor cells into mature Foxp3<sup>+</sup> Treg cells, but does not modulate the suppressive capacity of Treg cells. I $\kappa$ B<sub>NS</sub> associates with p50 and cRel on the Foxp3 promoter and the conserved non-coding

sequence 3 (CNS3) of the *Foxp3* gene and, thereby,  $I\kappa B_{NS}$  induces *Foxp3* expression. It was further suggested that  $I\kappa B_{NS}$  coordinates chromatin remodelling at the *Foxp3* locus via recruitment of histone modifying enzymes.<sup>134</sup> Taken together,  $I\kappa B_{NS}$  specifically regulates cytokine expression by modulating the NF- $\kappa$ B activity at certain promoters. Furthermore, it is important for the transition of Treg cell precursors to mature Treg cells via the induction of *Foxp3*.

### **1.10 Aims of the thesis**

The transcription factor NF- $\kappa$ B is essential in cell survival and development. Furthermore, NF- $\kappa$ B induces host defence during pathogenic invasion by activating the transcription of a broad range of proteins.<sup>93,95–97</sup> Diverse cancers, inflammatory and autoimmune diseases are initiated by a dysfunction of lymphocytes induced by a hampered NF- $\kappa$ B signalling<sup>95,135</sup>. For this reason NF- $\kappa$ B became an important target for pharmaceutical treatment<sup>95</sup>. Most promising are the members of the  $I\kappa B$  protein family, due to their ability to modulate the function of a specific NF- $\kappa$ B subunit or specific NF- $\kappa$ B pathways<sup>100,102,126,136</sup>. The aim of this thesis was to obtain a better understanding of the role of  $I\kappa B_{NS}$  in the regulation of NF- $\kappa$ B activity in health and disease.

Since  $I\kappa B$  proteins regulate the development and functionality of B and T cells, as well as the expression of cytokines, in this thesis it was analysed if  $I\kappa B_{NS}$  has an effect on the composition of the B cell subsets *in vivo*. Furthermore, it was investigated if  $I\kappa B_{NS}$  is involved in the TCR-triggered cell activation or the expression of NF- $\kappa$ B subunits. It is known that the nuclear  $I\kappa B\zeta$  is important in  $T_H17$  cell development and the expression of IL17A, therefore the involvement of  $I\kappa B_{NS}$  in  $T_H17$  cell differentiation was analysed *in vitro*. Furthermore, the effect of the  $I\kappa B_{NS}$  deficiency on the cytokine expression of  $T_H17$  cells was examined. The function of  $I\kappa B_{NS}$  within the progression of disease as well as  $T_H17$  cell formation was analysed/ examined by induction of EAE, DSS and transfer colitis in mice defective for  $I\kappa B_{NS}$  or by infecting these mice with *Citrobacter rodentium*.

## **2 Material and methods**

### **2.1 Molecular biological methods**

#### **2.1.1 Eukaryotic RNA or DNA extraction**

Eukaryotic primary cells were isolated and purified. RNA was isolated via the Qiagen RNeasy® Mini Kit and QIA shredder™ according to the supplier's manual. Afterward the RNA concentration was determined by absorption measurement at 260 nm with the spectrophotometer Nanodrop 1000 (peqlab).

Tail biopsies from mice were used for the isolation of PCR-ready DNA. The mouse tissue was lysed using the KAPA mouse genotyping hot start kit from peqlab as described in instruction manual. 1µl of the DNA-containing supernatant was used directly in polymerase chain reaction to determine the genotype of the particular mice.

#### **2.1.2 cDNA synthesis by reverse transcription**

For PCR analysis 100ng of the previously purified RNA (2.1.1) was transcribed into complementary DNA (cDNA) according to the protocol of the RevertAid™ Premium First Strand cDNA Synthesis Kit (Thermo Scientific). For RNA transcription oligo-dT primers were used. The cDNA-synthesis mix was incubated in the peqSTAR 96 Universal thermocycler (peqlab).

#### **2.1.3 Polymerase chain reaction**

After the reverse transcription step of mRNA into cDNA (2.1.2) or the isolation of DNA (2.1.1), the cDNA was amplified using the ready-to-use 2x KAPA2G Fast ReadyMix (peqlab). Like a normal wild-type Taq polymerase the KAPA2G Fast DNA polymerase has no proofreading activity and the specificity with 1 error per  $1.7 \times 10^5$  incorporated nucleotides is similar too. For one polymerase chain reaction (PCR) the components shown in Table 1 were mixed in the indicated order.

The PCR was performed in the peqSTAR 96 Universal thermocycler (peqlab) and various salt free primer (Eurofins MWG Operon, Table 2) were used to identify the expression of different genes. The chosen annealing temperature was 3 °C below the melting temperature ( $T_M$ ) of the particular primer pair. Below in Table 3 a usual PCR program is shown.

#### 2.1.4 Agarose gel electrophoresis

PCR products were separated by size by gel electrophoreses. Therefore a 1- 2 % agarose gel containing 0.5 µg/ml ethidium bromide in 1x TAE buffer (40 mM Tris Base, 20 mM acetic acid, 1 mM EDTA, pH 8.5) was prepared. For separation the gel electrophoresis system perfectBlue™ (peqlab) and the power supply EPS 301 (Amersham Bioscience) was used at 12V for 45- 60 min. The gel was documented in a gel documentation system from Intas via ultraviolet light (  $\lambda=254$  nm). The GeneRuler™ Low-Rage DNA ladder from Thermo Scientific was used to determine the DNA fragment size.

#### 2.1.5 Quantitative real-time detection PCR

For quantitative real-time detection PCR (qPCR)  $1 \times 10^6$  *in vitro* differentiated T cells (see 2.3.5 ) were harvested and washed. The RNA was isolated as described in 2.1.1 and used for cDNA syntheses (see 2.1.2 ). The cDNA was used as template in qPCR using the cyanine- dye SYBER Green (Roche). During the qPCR progression the SYBER Green intercalates into double-stranded DNA. The resulting DNA- fluorescent dye- complex is absorbing blue light (494 nm) and the emitted light was measured after each qPCR cycle. Ubiquitin C (UBC) was used as housekeeping gene for later normalisation. Measurements were run in duplicates using the LightCycler® 480 (Roche) system and the primers shown in Table 4. The qPCR was performed together with PhD student Carlos Plaza-Sirvent from the department Systems-oriented Immunology and Inflammation Research at the HZI (Braunschweig).

### 2.1.6 Transformation

For the transformation of plasmids into competent *E. coli* Top10 bacteria (Life technologies) the bacteria were thawed on ice. 100 to 200 ng plasmid DNA was added to the *E. coli*. The bacteria were incubated with the plasmid DNA at 42 °C for 30 sec followed by incubation on ice for 20 min. For heat shock the bacteria were incubated in a water bath at 42 °C for 30 sec followed by relaxing an ice for 2 min. After the addition of 500µl LB-medium (1% w/v tryptone, 0.5% w/v yeast extract, 85.6 mM NaCl, 1 mM NaOH) the bacteria were incubated at 37 °C, 800rpm in the Thermomixer comfort (Eppendorf) for 45 min. The bacteria were plated to LB-agar plates containing the suitable antibiotics (100 µg/ml ampicillin or 50 µg/ml kanamycin). The plates were incubated at 37 °C over night. The next day, colonies were picked into 5 ml LB medium and incubated at 37 °C, 280 rpm over night. 500 µl of the previous culture was inoculated into 200 µl LB-medium containing flasks and incubated at 37 °C, 180 rpm over night. The plasmid DNA was isolated using the QIAfilter™ Plasmid Maxi kit (Qiagen) following the suppliers manual. After isolation the DNA concentration was determined by absorption measurement at 260 and 280 nm using the Nanodrop 1000 spectrophotometer from peqlab.

### 2.1.7 Cell transfection and lentiviral transduction

A20 cells were stably transduced by lentiviral infection of shRNA (Table 5) which targets IκB<sub>NS</sub>. The IκB<sub>NS</sub> shRNA was generated and purchased by Addgene using the pLKO.1 (puro) cloning vector. The shRNA was cloned into the lentiviral vector pLKO.1 which were transfected together with the lentiviral envelop vector pMD2.G (Addgene) and the lentiviral gag-pol expression plasmide pCMV-dR8.2dvpr (Addgene) into HEK293T cells using JetPEI (polyplus transfection) according to the manufacturer's manual. After 24 h the medium (DMEM containing 10% fetal calf serum and 50 µg/ml penicillin/streptomycin) was exchanged. 48 h after transfection, the lentiviral particle were collected, filtered (0.45µm PVDF-Filter, Merck Millipore) and frozen. A20 cells were infected by adding 1ml lentiviral particle plus 8 µg/ml polybrene (Sigma Aldrich) to 2\*10<sup>6</sup> cells followed by centrifugation at 2,000 rpm at 25 °C for 2 h. After the incubation over night at 37 °C, stably transfected cells were selected by adding RPMI1640 (10% fetal calf serum, 50 µg/ml penicillin/ streptomycin, 0.05 mM β-mercaptoethanol) containing 5 µg/ml puromycin (Sigma Aldrich) for 2 weeks. The specific knockdown of IκB<sub>NS</sub> was verified by Western blotting.

I $\kappa$ B<sub>NS</sub> shDNA was also introduced to A20 cells by electroporation. Therefore cells were washed in the serum free medium Opti-MEM® (Invitrogen) and resuspended in 400  $\mu$ l of Opti-MEM®. After the transfer into a cuvette (gap size 4 mm, BTX® Harvard Apparatus), 10  $\mu$ g DNA was added and pulsed in a BioRad Gene Pulser® II with 300 V/ 700  $\mu$ F, high capacitance. Cells were transferred to cell culture flask with RPMI1640 (10% fetal calf serum, 50  $\mu$ g/ml penicillin/ streptomycin, and 0.05 mM  $\beta$ -mercaptoethanol) and led rest for one day, followed by a 2 weeks selection phase with 5  $\mu$ g/ml puromycin (Sigma Aldrich).

**Table 5: Small-hairpin (sh) RNA for I $\kappa$ B<sub>NS</sub> knock down.**

## 2.2 Protein biological approaches

### 2.2.1 Cell lysis and determination of protein concentration

To get the total-cell-lysate 5-10x10<sup>6</sup> cells were washed twice in 1x PBS (CaCl<sub>2</sub> and MgCl<sub>2</sub> free, invitrogen) and lysed in 50  $\mu$ l TPNE lysis buffer (Table 6 ) with 1 mM phenylmethylsulfonyl fluoride (PMSF), 1x protease inhibitor mix (Table 6 ) and 0.4 mM

sodium orthovanadate (Sigma-Aldrich). The cell buffer mix was incubated for 20 min on ice followed by centrifugation at 14,000 rpm, 4 °C for 15 min in an Eppendorf table centrifuge 5417R. The supernatant was transferred into a new reaction tube for following experiments.

**Table 6: Cell lysis buffers and additives.**

<b>Buffer or additive</b>	<b>Contents</b>
<b>TPNE lysis buffer</b>	1x PBS (invitrogen) 300 mM NaCl 2 mM EDTA 1 % v/v Titron X-100
<b>100x protease inhibitor mix</b>	100 µg/ml aprotinin 100 µg/ml leupeptin 100 µg/ml pepstatin A 100 µg/ml chymostatin

The protein concentration of the lysate was determined by bicinchoninic acid (BCA) assay as described in the supplier's manual (Thermo Scientific). The protein concentration was detected in the Infinite M200 microplate- reader (TECAN) by absorbance measurement at 562 nm.

### 2.2.2 Fractionated cell lysis

To get cytoplasmic and nuclear proteins separated from each other a two step lysis was performed. For the cytoplasmic extracts the washed cells were lysed for 10min on ice in buffer A (10 mM HEPES, pH 7.9, 1.5 mM MgCl<sub>2</sub>, 10 mM KCl, 300 mM sucrose, 0.5 % NP-40) supplemented with 1 mM phenylmethylsulfonyl fluoride (PMSF), 1x protease inhibitor mix (Table 6 ) and 0.4 mM sodium orthovanadate (Sigma-Aldrich). After centrifugation (15 min, 2500 g) the supernatant representing the cytoplasmic fraction was transferred into a new reaction tube for following experiments. The pellet was washed two times in 500µl buffer A and resuspended in buffer B (10 mM HEPES, pH 7.9, 5 mM MgCl<sub>2</sub>, 100 mM KCl, 1 mM DTT, 10 % glycerol, 0.1 % NP-40) again supplemented with 1 mM phenylmethylsulfonyl fluoride (PMSF), 1x protease inhibitor mix (Table 6 ) and 0.4 mM sodium orthovanadate (Sigma-Aldrich). The nuclear pellets were sonicated in three cycles of 15 sec sonication at the highest power setting plus 15 sec chilling using a Bioruptor™ NextGen (Diagenode). Residues of the nuclear wall were removed by

centrifugation for 5 min, 10,500 g at 4 °C. The nuclear fraction was transferred into a new reaction tube for following experiments.

### 2.2.3 SDS-polyacrylamide gel electrophoresis (SDS-PAGE)

For protein separation via SDS-polyacrylamide gel electrophoresis (SDS-PAGE) 20-40 µg of the protein lysate was mixed with 5x reducing sample buffer (RSB, Table 7 ) to a final concentration of 1x RSB. The RSB-lysate mix was boiled for 5 min at 95 °C.

**Table 7: SDS-Page buffers.**

<b>Buffer or additive</b>	<b>Contents</b>
<b>5x reducing sample buffer (RSB)</b>	50 mM Tris, pH 6.8 50 % v/v glycerol 10 % w/v SDS 25 % v/v β-mercaptoethanol 0.25 mg/ml bromphenol blue
<b>1x Running buffer</b>	25 mM Tris, pH 8.0 192 mM glycerol 1 % v/v SDS

Proteins were separated in a 12 % polyacrylamide gel (Table 8) in 1x running buffer (Table 7) at 80-120 V using BioRad "Tetra Cell". To determine different protein sizes the standard PageRuler™ protein ladder (Thermo Scientific) was used.

**Table 8: Composition of a 12 % polyacrylamide gel.**

<b>Solution</b>	<b>Concentration</b>
<b>Water</b>	0.33 %
<b>30 % acrylamide mix (Rotiphorese® Gel 30)</b>	12 %
<b>1.5 M Tris (pH 8.8)</b>	3.75 mM
<b>10 % SDS</b>	0.1 %
<b>10 % APS</b>	0.1 %
<b>TEMED (99% p.a.)</b>	0.04 %

For further analysis the proteins were blotted onto a PVDF membrane (see 2.2.4 ) or the gel was stained with Coomassie Brilliant Blue (BioRad). To prepare the SDS-PAGE gel for Coomassie® Brilliant Blue staining the gel was washed 3 times for 10 min in MilliQ

water. The Coomassie® Brilliant Blue solution was added to the gel for 1 to 2 hours followed by five washing steps or washing over night to remove background staining.

#### 2.2.4 Western blotting

Proteins separated by SDS-PAGE were transferred to PVDF membrane (GE Healthcare) using a BioRad "Criterion Blotter" in 1x transfer buffer (Table 9 ) at 80 V for 1- 1.5 h. Afterwards the membrane was incubated in blocking buffer (Table 9 ) for 1h at room temperature (RT) followed by the incubation in primary antibody (Table 10, with reactivity against hu- human, ms- mice, rt- rat ) diluted in blocking buffer over night at 4 °C.

**Table 9: Buffers for Western blotting.**

<b>Buffer or additive</b>	<b>Contents</b>
<b>1x Transfer buffer</b>	25 mM Tris, pH 8.0 192 mM glycerol 20 % v/v methanol
<b>10x TBS</b>	137 mM NaCl 2.68 mM KCl 24.76 mM Tris
<b>Blocking buffer</b>	1x TBS 5 % w/v non-fat dry milk 0.05 % v/v Tween-20
<b>Wash buffer</b>	1x TBS 0.05 % v/v Tween-20

The next day the membrane was washed three times 10 min in wash buffer to remove unbound antibodies. After the incubation in horseradish peroxidase-conjugated secondary antibodies (1 h, RT, Table 11 ) the membrane was washed as described above. Finally, the membrane was incubated with chemiluminescent substrates of Thermo Scientific, SuperSignal® West Dura Extended Duration Substrate or SuperSignal® West Femto Maximum Sensitivity and developed in the Fusion FX-7 camera (Vilber Lourmat). If required, the volume of bands were quantified with the program BIO-1D (Peqlab). For further re-use of the blotted membrane the bound antibodies were removed by using the ReBlot plus mild antibody stripping solution from Merck Millipore according to the company's protocol. For the re-use of blotted membrane with anti- phosphorylated protein antibodies the background of the first anti-phosphorylated protein antibody was reduced by

the incubation with 1 % azide solution in washing buffer for 35 min. After re-blotting the membrane was blocked again in blocking buffer.

**Table 10: Primary antibodies for Western blotting.**

### 2.2.5 Urea-PAGE

To test proteins for their dimer stability the samples were prepared as described in 2.2.3. SDS- PAGE and Urea- PAGE have the same composition except that the Urea- PAGE gel additionally contains 6M urea in both the stacking and the separating gel. For further analysis the proteins were blotted onto a PVDF membrane (see 2.2.4).

### 2.2.6 Immunoprecipitation

To get a enrichment of a particular protein out of a cell lysat a immunoprecipitation was performed. Protein A sepharose beads (30µl of 1x PBS containing 50% protein A sepharose, Sigma Aldrich) were washed three times with 500µl 1x PBS (invitrogen). Zentrifugation steps were performed at 4 °C, 6000rpm for 1min. 200µl lysis puffer with 2µg IκB<sub>NS</sub> antibody (selfmade, mouse IgG2b or rabbit IgG IκB<sub>NS</sub> antibody) were added to the beads. After the incubation (4 h, rotation at 4 °C) the protein A sepharose beads were washed three times with 500µl lysis buffer. A20 cells (B cell line) were lysed as described in 2.2.1 or 2.2.2 and the lysate was added to the antibody labelled beads. The labelled protein A sepharose beads and the cell lysate were incubated over night while rotating at 4 °C. The beads were washed three times with 500µl 1x PBS (invitrogen) to get rid of

unbound protein. The beads were re-suspended in 20µl 1x RSB (Table 7), incubated for 5 min at 95 °C and analysed by SDS-PAGE and Western blotting (2.2.3 and 2.2.4).

### **2.2.7 MicroLink™ Protein Coupling Kit**

To get an enrichment of a particular protein free from antibody contamination the MicroLink™ Protein Coupling Kit from Thermo Scientific was used. According to the manual rabbit IκB<sub>NS</sub> antibodies or rabbit IgG antibodies were bound to the column. For the coupling of rabbit IκB<sub>NS</sub> antibody 300µl of a 1mg/ml solution (in binding buffer) and for the rabbit IgG antibody 600µl of a 0.5mg/ml solution (in binding buffer) was used.  $1.5 \times 10^8$  cells were lysed (2.2.1) in 2ml TPNE lysis buffer (Table 6 ) with 1 mM phenylmethylsulfonyl fluoride (PMSF), 1x protease inhibitor mix (Table 6 ) and 0.4 mM sodium orthovanadate (Sigma-Aldrich), the lysate was added to the affinity column. After incubation and elution steps as described in the instruction manual the eluate was analysed in SDS-PAGE and western blotting assay (2.2.3 and 2.2.4) or the SDS-PAGE gel was stained with Coomassie Brilliant Blue (BioRad, 2.2.3).

## **2.3 *In vitro* techniques**

### **2.3.1 Cultivation of A20 cell line**

The B cell line named A20 was cultured in culture flasks, 6-well, 12-well or 96-well (NUNC- Thermo Scientific) in the incubator HERAcCell 240i (Thermo Scientific) at 37 °C, 5% CO<sub>2</sub>, and 95% air humidity. The A20 cells were cultured in RPMI 1640 (Gibco) supplemented with 10% fetal calf serum (FCS, PAA), 50 µg/ml penicillin/ streptomycin (Gibco), and 0.05 mM β-mercaptoethanol (Gibco). For the handling of the cell line the following materials were used: 1.5 ml and 2 ml reaction tubes (Sarstedt), sterile 10 µl, 200 µl and 1000 µl pipette tips (Starlab), 5 ml, 10 ml and 25 ml pipettes (Sterilin - Thermo Scientific), 15 ml and 50 ml reaction tubes (Greiner-bio-one), 45 µm and 22 µm sterile syringe filters (Merck Millipore), centrifuges 5810R (Eppendorf). Cells were handled in sterile hoods SterilGARD® III Advance (The Baker Company). Cell numbers were determined by Neubauer improved cell counting chambers (BRAND scientific) or Cellometer™ Auto T4 (Nexcelom).

### 2.3.2 Organ isolation and single cell suspension preparation

For the removal of murine lymphoid organs like the peripheral lymph nodes (pLN), mesenteric lymph nodes (mLN) and the spleen mice were euthanised by carbon dioxide inhalation. The organs were collected in 1xPBS (invitrogen) containing 0.2 % BSA. A 70  $\mu\text{m}$  nylon mesh was used for the homogenisation of the organs. After a washing step with 1x PBS containing 0.2 % BSA the erythrocytes were removed by the incubation with ACK lysis buffer (0.15 M  $\text{NH}_4\text{Cl}$ , 1 mM  $\text{KHCO}_3$ , 0.1 mM EDTA, pH 7.3) for 2 min at room temperature. After another washing step the primary cells were used for the isolation of naïve T cells by flow cytometry (2.3.4) or directly in cell culture. The primary cells were cultured in primary T cell medium (Table 12) till further use.

**Table 12: Composition of primary T cell medium.**

<b>Additive</b>	<b>Concentration</b>	<b>Company</b>
<b>IMDM</b>		Gibco
<b>Fetal calf serum</b>	10 %	Biochrom
<b>Penicillin/streptomycin</b>	50 $\mu\text{g/ml}$	Gibco
<b>HEPES</b>	25 mM	Biochrom
<b><math>\beta</math>-Mercapthoethanol</b>	0.05 mM	Gibco
<b>Non-essential amino acids</b>	1 %	Gibco
<b>Sodium pyruvate</b>	1 mM	Gibco

### 2.3.3 Flow-cytometric analysis

For the cell analysis via flow cytometry cells were harvested and  $1 \times 10^6$  cells were washed twice in 1 ml 1x PBS (invitrogen). All centrifugation steps were performed at 4 °C, 1500 rpm for 5 min. A live/dead staining was performed in 100  $\mu\text{l}$  1x PBS (invitrogen) containing one of the LIVE/DEAD® dyes from Life technologies (Table 13, 30 min, 4 °C, in the dark).

Previously to surface staining the cells were washed again. Surface markers were stained with fluorochrome-conjugated antibody (Table 14) in flow cytometry buffer (1x PBS, 2% w/v BSA, 0.01% v/v  $\text{NaN}_3$ ) at 4 °C, for 15 to 20 min in the dark. By a following wash step with flow cytometry buffer unbound antibodies were washed away.

**Table 13: Fluorescent dyes for flow cytometric analysis.**

<b>Dye</b>	<b>Excitation</b>	<b>Emission</b>	<b>Company</b>
LIVE/DEAD® near IR fluorescent reactive dye	750 nm	775 nm	Life technologies
LIVE/DEAD® Blue fluorescent reactive dye	350 nm	450 nm	Life technologies
LIVE/DEAD® aqua fluorescent reactive dye	367nm	526	Life technologies

If intracellular cytokine staining is requested the cells were stimulated for 4 hours with phorbol myristate acetate (PMA, 10 ng/ml, Sigma Aldrich) and ionomycin (1  $\mu$ M, Sigma Aldrich). For the last 2 hours Brefeldin A (10  $\mu$ g/ml, Sigma Aldrich) was added as well. Afterwards the cells were fixed and permeabilised using the Foxp3 Staining Buffer Set (Miltenyi Biotech). To prepare a fixation/ permeabilisation working solution one part Fixation/ Permeabilisation Concentrate was diluted with three parts Fixation/ Permeabilisation Diluent. Cells were incubated with 100  $\mu$ l fixation/ permeabilisation working solution for 30 min (4 °C, in the dark) and washed with 1 ml 1x permeabilisation buffer prepared from 10x permeabilisation buffer with deionised/ distilled water. The intracellular cytokine staining was performed in 100  $\mu$ l 1x permeabilisation buffer with the according amount of ROR $\gamma$ , IFN $\gamma$  and/or IL17A antibody (4 °C, for 30 min in the dark, Table 14). Finally cells were washed in 1x permeabilisation buffer and used in flow cytometry analysis. The labelled cells were analysed via the BD™ LSR II Flow Cytometer System or the BD LSRFortessa™ (BD Bioscience).

To assay apoptosis in flow cytometry analysis cells were washed in 1x PBS and incubated in 250 $\mu$ l Nicoletti buffer (2% v/v Triton X-100, 0.1% C<sub>6</sub>H<sub>5</sub>Na<sub>3</sub>O<sub>7</sub>, 50  $\mu$ g/ml PI) for at least 1 h at 4 °C in the dark. After flow cytometric measurement cells with sub-G1 DNA were quantified.

### 2.3.4 Cell isolation by flow cytometry

As described before lymph nodes and spleens were isolated (2.3.1) and stained with surface markers (2.3.3). In cooperation with Dr. Lothar Groebe (flow cytometry facility of the Helmholtz Center for Infection Research, Braunschweig, Germany) the cells were isolated in the FACS Aria II (BD Bioscience) or the MoFlo (Beckman and Coulter). Cells were collected in tubes containing 1ml 1xPBS with 0.2 % BSA.

### 2.3.5 *In vitro* generation of T helper cell subsets

CD4<sup>+</sup>CD62L<sup>high</sup>CD25<sup>-</sup> naïve T cells were isolated as described in 2.3.4 and re-suspended in primary T cell medium (Table 12). Per 96- well 2\*10<sup>5</sup> cells were activated with plate bound anti-CD3 and anti-CD28 (Table 15) or Dynabeads® Mouse T-Activator CD3/CD28 (invitrogen) in a ratio of 1 to 1.25 were used. The cells were cultured in the presence of priming cytokines and inhibitory antibodies according to the respective T helper subset (Table 15). At day 4 or 5 the cells were analysed.

**Table 15: Additives for T helper cell polarisation.**

<b>T<sub>H</sub> subset</b>	<b>Additive</b>	<b>Concentration</b>	<b>Clone</b>	<b>Company</b>

### **2.3.6 *In vitro* expansion of CD4<sup>+</sup>CD25<sup>-</sup> T cells**

After isolation of CD4<sup>+</sup>CD25<sup>-</sup> T cells (2.3.4) 4\*10<sup>6</sup> of these cells were expanded. First cells were re-suspended in 4 ml RPMI supplemented with 10 % FCS (PAA), 1mM sodium pyruvate (Gibco), 1x non-essential amino acids (Gibco), 50 ng/ml penicilline/ streptomycin (Gibco) and 50 µM β-mercaptoethanol (Gibco). The CD4<sup>+</sup>CD25<sup>-</sup> T cells were stimulated in a 6-well plate with 1 µg/ml plate bound anti-CD3 and 2 µg/ml soluble anti-CD28 in the present of 10 ng/ml murine IL2. At day 3, cells were transferred to a 10-cm dish into a total volume of 15ml fresh RPMI with supplements (10 % FCS, 1mM sodium pyruvate, 1x non-essential amino acids, 50 ng/ml penicilline/ streptomycin and 50 µM β-mercaptoethanol). Cells were used on day 6 for activation analysis (2.3.7).

### **2.3.7 *In vitro* activation of *ex vivo* or expanded T cells**

CD4<sup>+</sup> or CD8<sup>+</sup> T cells were isolated by cell isolation (2.3.4) and used directly in activation assay or isolated CD4<sup>+</sup> were expanded (2.3.6) before. 5\*10<sup>6</sup> to 10\*10<sup>6</sup> cells were seeded into a 12-well plate and centrifuged down for 2 min, 800rpm at room temperature. Cells were either stimulated with coated anti-CD3 (10µg/ml) plus anti-CD28 (5µg/ml) or PMA (10 ng/ml) plus ionomycin (1 µM) or left untreated. Anti-CD3/CD28 stimulation was performed for 15 min, 30 min, 1 h, 2 h and 4 h or the cells were stimulated for 2 hours with PMA/ ionomycin. After harvesting the cells were washed two times with 1x PBS and lysed for Western Blot (2.2.1, 2.2.3 and 2.2.4).

### **2.3.8 Proliferation analysis with alamarBlue®**

To quantitatively measure the proliferation of IκB<sub>NS</sub> knockdown A20 cells alamarBlue® was used. AlamarBlue® is an indicator dye containing an oxidation- reduction indicator that changes the fluorescence as well as the colour upon chemical reduction of the culture medium. 1\*10<sup>4</sup> A20 cells were plated to a 96-well. One-tenth of the volume of the well AlamaBlue® was added. The A20 cells were cultured for 8 h to 7 days. Absorbance was measured at 570nm and 600nm using Infinite M200 microplate- reader (TECAN). The percentage of reduction of alamarBlue® was calculated as described in the supplier manual.

---

### **2.3.9 Proliferation analysis via CFSE or CellTrace™ Violet Proliferation Dye staining**

To analyse the proliferation of T cells naïve T cells were isolated (2.3.4). Prior to the cultivation the cells were stained with carboxyfluorescein succinimidyl ester (CFSE, eBioscience) or CellTrace™ Violet Proliferation dye (Invitrogen). Therefore, T cells were washed two times with 1x PBS (Invitrogen) and re-suspended in 1xPBS to a concentration of  $2 \times 10^6$ /ml. CFSE or CellTrace™ Violet Proliferation Dye were added to a final concentration of 5  $\mu$ M/ml. Cells were incubated for 10 min (CFSE) or 20 min (Violet Proliferation Dye) at 37 °C in the dark. After two washing steps with pre-warmed medium cells were cultured (2.3.5). At day 4 cells were stained for surface markers and intracellular proteins as in 2.3.3 and analysed in flow cytometry.

### **2.3.10 Enrichment of T<sub>H</sub>17 cells via mouse IL17 Secretion Assay**

As described in 2.3.4 and 2.3.5 naïve T cells were isolated and cultured under T<sub>H</sub>17 polarising conditions. At day 4 the cells were stimulated with PMA (10ng/ml, Sigma Aldrich) and ionomycin (1  $\mu$ M, Sigma Aldrich) for 3 hours at 37 °C. For the following enrichment of IL17 positive cells the mouse IL17 secretion assay from Miltenyi was used. Two washing steps with MACS buffer (1x PBS, pH 7.2, 0,5% bovine serum albumin, 2mM EDTA) were performed before the cells were coated with a mouse IL17 catch reagent (directed to CD45). For the IL17 secretion period of 45 min the cells were diluted with warm medium and  $1 \times 10^7$  cells in 15 ml medium were incubated in a 15 ml Falcon tube under slow continuous rotation using a MACSmix Tube Rotator. The cells were further incubated with IL17 detection antibodies (biotin labelled), Biotin-PE antibodies and anti-PE MicroBeads followed by a magnetic separation according to the supplier instructions manual. Isolated cells were used to analyse cytokine secretion as described in 2.3.11 or 2.3.12.

### **2.3.11 Analyses of cytokine expression by Proteom Profiler™ Array**

To analyse the cytokine secretion IL17 secreting cells were enriched like in 2.3.10 and  $0.8 \cdot 10^6$  cells were stimulated with PMA (10ng/ml, Sigma Aldrich) and ionomycin (1 $\mu$ M, Sigma Aldrich). After 4 hours the supernatant was taken and used for cytokine analysis using the Proteom Profiler™ Array (R&D Systems). The array membrane was activated and afterwards incubated with the T<sub>H</sub>17 supernatant as described in the user manual. Finally, the chemiluminescence of the membrane was measured in the Fusion FX-7 camera (Vilber Lourmat) and the volume of bands were quantified with the program BIO-1D (Peqlab).

### **2.3.12 Analyses of cytokine expression by FlowCytomix Kit**

To analyse the cytokine secretion of T<sub>H</sub>17 cells by flow cytometry IL17 secreting cells were enriched (2.3.10) and  $0.8 \cdot 10^6$  cells were stimulated with PMA (10ng/ml, Sigma Aldrich) and ionomycin (1 $\mu$ M, Sigma Aldrich). After 4 hours the supernatant was taken and used for cytokine analysis via FlowCytomix kit from eBioscience. The supernatant was used directly or after 1:10 or 1:50 dilution. The mouse T<sub>H</sub>1/T<sub>H</sub>2/T<sub>H</sub>17/T<sub>H</sub>22 13plex Kit FlowCytomix (eBioscience) was combined with five Simplex FlowCytomix kits (eBioscience) required to measure the cytokine secretion of GM-CSF, IL1 $\beta$ , IL17F, IL23 and MIP1 $\alpha$  simultaneously with the secretion of the 13plex kit cytokines (IFN $\gamma$ , IL1 $\alpha$ , IL2, IL4, IL5, IL6, IL10, IL13, IL17A, IL21, IL22, IL27 and TNF $\alpha$ ). According to the product information the standard curves and samples were prepared and measured by flow cytometry in the BD™ LSR II Flow Cytometer System or the BD LSRFortessa™ (BD Bioscience).

## **2.4 *In vivo* techniques**

### **2.4.1 Mouse strains**

The mice line B6.129/SV-NFKBID(tm1Clay), later named as I $\kappa$ B<sub>NS</sub>-mice were a kind gift of Prof. Dr. Linda Clayton from the Harvard Medical School (Boston, USA)<sup>128</sup>. The B6.PL-Thy1<sup>a</sup>/CyJ-mice provided by René Teich from the Helmholtz-Centre for Infections Research (Braunschweig, Germany) was later designated as Thy1.1-mice<sup>137</sup>. Both mice lines were bred under specific pathogen free (SPF) conditions in the animal facility of the Helmholtz-Center for Infection Research (Braunschweig, Germany).

B6.129S7-Rag1<sup>tm1M<sup>om</sup></sup>-mice, later referred to as RAG1-mice were bred at the animal facility of the Charité (Berlin, Germany)<sup>138</sup>.

#### **2.4.2 Dextran sulphate sodium induced chronic colitis (chronic DSS colitis)**

To induce murine colitis mice were fed in three cycles with drinking water containing 2% (w/v) dextran sodium sulfate (DSS) for 7 days followed by 14 days feeding with DSS- free water. The inflammation of the colon was assessed at the end of the last cycle. During the progression of colitis the body weight was measured. The consistency of the stool and the rectal bleeding were scored as shown in Table 16. After the three cycles of DSS treatment the length of the colon was measured from the caecum to the anus. Colon samples were fixed in 4% paraformaldehyde. The fixed colon samples were embedded in paraffin and were cut in 2 µm sections. The colon sections were deparaffinised, stained with hematoxylin and eosin (H&E- staining) and scored in a blinded manner. The histological score of the DSS colitis is the sum of the individual scores for inflammatory cell infiltrations and tissue damage as depicted in Table 16. The DSS colitis was performed in cooperation with Dr. Rainer Glaubien and Dr. Anja A. Kühl from the Charité, Berlin (Germany).

#### **2.4.3 Adoptive transfer colitis**

For adoptive transfer colitis CD4<sup>+</sup>CD25<sup>-</sup> T cells were isolated from the spleen and lymph nodes of I $\kappa$ B<sub>NS</sub> wildtype or knockout mice using MACS separation kits (CD4 T cell isolation kit, CD25-PE Kit, Miltenyi) as described in suppliers manual. 5\*10<sup>5</sup> cells in 200µl 1x PBS were injected intraperitoneally into RAG1 mice.

**Table 16: Scoring in DSS and transfer colitis.**

Score	Symptoms		
	Stool consistency	Rectal bleeding	Colon
<b>0</b>	Well formed pellets	No hemocult	No changes
<b>1</b>			<ul style="list-style-type: none"> <li>• Minimal scattered mucosal inflammatory cell infiltrates</li> <li>• With or without minimal epithelial hyperplasia</li> </ul>
<b>2</b>	Pasty and semi-formed, did not adhere to the anus	Positive hemocult	<ul style="list-style-type: none"> <li>• Mild scattered to diffuse mucosal cell infiltrates, sometimes extending into submucosa and associated with erosions</li> <li>• With minimal to mild epithelial hyperplasia, with minimal to mild mucin depletion from goblet cells</li> </ul>
<b>3</b>			<ul style="list-style-type: none"> <li>• Mild to moderate cell infiltrates that were sometimes transmural, often associated with ulceration</li> <li>• With moderate epithelial hyperplasia and mucin depletion</li> </ul>
<b>4</b>	Liquid, did adhere to the anus	Gross bleeding	<ul style="list-style-type: none"> <li>• Marked inflammatory cell infiltrates that were often transmural and associated with ulceration</li> <li>• With marked epithelial hyperplasia and mucin depletion</li> </ul>
<b>5</b>			<ul style="list-style-type: none"> <li>• Marked transmural inflammation with severe ulceration</li> <li>• With loss of intestinal glands</li> </ul>

The body weight was monitored during colitis progression. The consistency of the stool and the rectal bleeding were scored as shown in Table 16. The length of the colon was measured from the caecum to the anus and colon samples were fixed in 4 % paraformaldehyde, embedded in paraffin, cut in 2  $\mu$ m sections, deparaffinised, stained with hematoxylin and eosin (H&E- staining) and scored in a blinded manner. The transfer colitis histological score is the sum of the individual scores for inflammatory cell infiltrations and tissue damage as depicted in Table 16. The transfer colitis was performed in cooperation with Dr. Rainer Glauben and Dr. Anja A. Kühl from the Charité, Berlin (Germany).

#### 2.4.4 *Citrobacter rodentium* infection

Mice were infected with the *Citrobacter rodentium* strain ICC180 (courtesy from S. Wiles). *C. rodentium* were cultured in Lennox broth (LB) medium (ROTH) at 37 °C overnight. The next day the 9 fold volume of medium was added. After 1.5 h the optical density (OD) was measured. The bacteria were adjusted to  $1 \times 10^{11}$  colony forming units (CFU) in 1ml 1x PBS. Mice were administered orally with  $1 \times 10^{10}$  *C. rodentium* and were analysed at day 10 post infection. The body weight was monitored during progression of infection. At day 10 the length of the colon was measured from the caecum to the anus. The stool was collected in 1 ml LB, weighted, smashed and diluted serially to detect the bacterial load in faeces. Serial dilutions were added onto MacConkey Agar (ROTH) and cultured at 37 °C for 24 h. CFU were counted and bacterial burden was normalised to stool weight. To determine the bacterial load in organs liver and spleen were homogenised, serial dilutions were plated onto MacConkey Agar plats and incubated at 37 °C for 24 h before counting. To isolate cells from lamina propria colons were placed into 15 ml ice-chilled 0.5 mM EDTA for 30min (on ice) followed by sufficient rinsing with 1x PBS to remove residual epithelium. Afterward tissue was cut into fine pieces and digested in DMEM medium (Gibco) supplemented with 1 mg/ml collagenase D (Roch) and 0.1 mg/ml DNase I (Roch) three times for 30min at 37 °C. After each round of incubation cells were suspended by passing through a 100 µm mesh. After centrifugation cell pellet was re-suspended in a 40% isotonic Percoll solution (GE Healthcare) and underlaid with an 80% isotonic Percoll solution. After centrifugation at 900xg at room temperature for 20 min lamina propria lymphocytes (LPLs) were yielded from the interface cell ring of the 40-80% Percoll gradient. Cells were then washed with PBS containing 2% FCS and used for further studies. For flow cytometric analysis cells from spleen and mLN as well as LPLs were re-stimulated in medium containing IL23 (20ng/ml) with PMA (10 ng/ml, Sigma Aldrich) and ionomycin (1 µg/ml, Sigma Aldrich) for 6 hours. For the last 3 hours Brefeldin A (10 µg/ml, Sigma Aldrich) was added as well. Cells were processed for flow cytometry as previously described (2.3.3) with a Fc-block step (10min, on ice), which was included after cell surface staining. For the intracellular flow cytometry staining the fixation/ permeabilisation buffers from eBioscience were used. For histology, whole colon samples were placed in a shape of 'swiss rool' and fixed in 4 % Rosto-HistoFix (Roth), embedded in paraffin, cut in 8 µm sections, deparaffinised, stained with hematoxylin and eosin (H&E- staining) and scored in a blinded manner. The histological sections were analysed for epithelial hyperplasia, epithelial integrity and mononuclear cell infiltration

(Table 17). The maximal score that could result from scoring was 9. Samples were imaged with a microscope from Carl Zeiss and progressed with the software Nuance2.10.0 (Carl Zeiss, Inc.). The *Citrobacter rodentium* infection was performed in cooperation with Zuobai Wang (Institute for infection immunology, TWINCORE, Hannover, Germany).

**Table 17: Histological scoring in *Citrobacter rodentium* infection**

Score	Symptoms		
	Epithelial hyperplasia	Epithelial integrity	Mononuclear cell infiltration
0	No change	No change	No change
1	1- 50%	Mild epithelial ulceration and cryptic destruction	Mild
2	51- 100%	Moderate epithelial ulceration and cryptic destruction	Moderate
3	100%	Severe epithelial ulceration and cryptic destruction	Severe

#### 2.4.5 Experimental autoimmune encephalomyelitis (EAE)

Experimental autoimmune encephalomyelitis (EAE) the mouse model of multiples sclerosis was induced in 10-12 weeks old mice. Mice were injected subcutaneously at four sites with a 200µl of a 1:1 emulsion of 200µg/200µl MOG(35-55)- peptide (resolved in 1x PBS, MEVGWYRSPFSRVVHLYRNGK) and complete Freund's Adjuvant (CFA) with 4mg/ml *Mycobacterium tuberculosis*. Additionally, the mice were injected intraperitoneally (i.p.) with 200ng pertussis toxin in 200µl (in 1x PBS) to open the blood- brain- barrier. At day 2 the i.p. injection of pertussis toxin was repeated. From day 3 to 40 the mice were monitored daily for clinical EAE signs according to the Table 18. Mice with a score higher 3 were sacrificed.

**Table 18: Scoring of the clinical symptoms of EAE.**

<b>Score</b>	<b>Symptom</b>
<b>0</b>	None
<b>0.5</b>	Partial limp tail
<b>1</b>	Limp tail
<b>2</b>	Delayed rotation from dorsal position
<b>2.5</b>	Hindlimp weakness
<b>3</b>	Complete hindlimp paralysis
<b>3.5</b>	Starting foreleg weakness
<b>4</b>	Paralysis of one foreleg
<b>5</b>	Moribund, death

## 2.5 Statistics

The Graph Pad Prism Software (GraphPad Software) was used for all statistical analyses. To determine statistical significance two-tailed Mann-Whitney U test was used and error bars represent the standard error of the mean (SEM).

### 3 Results

#### 3.1 Characterisation of $I\kappa B_{NS}$ -deficient mice

##### 3.1.1 The loss of $I\kappa B_{NS}$ affects the $B220^+$ B cells frequency but not apoptosis sensitivity

The transcription factor NF- $\kappa$ B was first identified in B cells as a protein regulating the expression of the  $\kappa$ B light chain<sup>139</sup>. The deletion of members of the NF- $\kappa$ B protein family affects proliferation and function of B cells<sup>140,141</sup>. Further, a dysregulation of NF- $\kappa$ B subunits leads to a variety of B cell cancers like Hodgkin's disease<sup>142</sup> and large B cell lymphoma<sup>143</sup>.

**Figure 6: Flow cytometric analysis of bone marrow derived B cell subsets of  $I\kappa B_{NS}^{+/+}$  and  $I\kappa B_{NS}^{-/-}$  mice.** Bone marrow cells of wildtype (upper panel) and  $I\kappa B_{NS}$ -deficient (lower panel) animals were stained with antibodies directed against B220, CD21, CD23 and IgM. Dot blots show mature ( $B220^+CD23^+CD21^+IgM^-$ ), T1 ( $B220^+CD23^-CD21^-IgM^+$ ), T2 ( $B220^+CD23^+CD21^+IgM^+$ ) and MZ ( $B220^+CD23^-CD21^+IgM^+$ ) B cells. Representative dot plots from one of two independent experiments are shown.

To determine the function of the NF- $\kappa$ B regulator  $I\kappa B_{NS}$  in B cells, the frequencies of  $B220^+$ ,  $B220^+CD23^{low}$  (including marginal zone and T1 B cells), marginal zone (MZ,

B220<sup>+</sup>CD23<sup>-</sup>CD21<sup>+</sup>IgM<sup>+</sup>), T1 (B220<sup>+</sup>CD23<sup>-</sup>CD21<sup>+</sup>IgM<sup>+</sup>), B220<sup>+</sup>CD23<sup>+</sup> (including mature and T2 B cells), mature (B220<sup>+</sup>CD23<sup>+</sup>CD21<sup>+</sup>IgM<sup>+</sup>) and T2 (B220<sup>+</sup>CD23<sup>+</sup>CD21<sup>+</sup>IgM<sup>+</sup>) B cells as well as the cell viability were analysed *ex vivo* (Figure 6 and Figure 7). To characterise the B cell compartment of IκB<sub>NS</sub>-defective and wildtype mice, bone marrow (Figure 6 and Figure 7A) and blood (Figure 7B) were stained and analysed by flow cytometry. The dot blots of the flow cytometric measurement of IκB<sub>NS</sub>-deficient mice indicated a reduced frequency in each analysed bone marrow-derived B cell subset as well as total B cells (B220<sup>+</sup> cells) compared to wildtype mice (Figure 6). Statistical analyses of these flow cytometric data revealed a significantly reduced frequency of B220<sup>+</sup> cells in bone marrow (Figure 7A) of IκB<sub>NS</sub>-deficient compared to wildtype mice. Furthermore, IκB<sub>NS</sub> deficiency induced a reduction of the B220<sup>+</sup> B cell frequency in the blood (Figure 7B). In contrast, an equal frequency of viable cells was observed in bone marrow (Figure 7A) and blood (Figure 7B) as well as a similar frequency of B220<sup>+</sup> CD23<sup>low</sup>, MZ, T1, B220<sup>+</sup> CD23<sup>+</sup>, mature and T2 B cells in bone marrow (Figure 7A). Thus, IκB<sub>NS</sub> contributes to the development and/or survival of B220<sup>+</sup> B cells, but the defect induced by IκB<sub>NS</sub> deficiency is not reflected in one specific subset.

**Figure 7: B220<sup>+</sup> B cell levels are reduced in IκB<sub>NS</sub>-deficient mice.** Bone marrow (A) or blood (B) cells of wildtype and IκB<sub>NS</sub>-deficient animals were stained with antibodies directed against B220 (A-B), CD21, CD23 and IgM (A) followed by flow cytometry analysis. Error bars display the standard error of the mean (s.e.m.) of four (B) or six (A) animals per genotype of two independent experiments. Statistical analyses were performed by two-tailed Mann-Whitney U test; (\*) p<0.05.

Grumont *et al.* reported that the deficiency of NF- $\kappa$ B1 cause a proliferation defect in B cells by cell cycle arrest in the G1-phase and enhanced mitogen-induced apoptosis<sup>141</sup>. Furthermore, the deletion of cRel impairs B and T cell division and leads to an activation-associated proliferation defect<sup>140</sup>. In T cells, this proliferation defect is due to inadequate amounts of IL2, which in turn is crucial for *in vivo* induction of Treg but not T<sub>H</sub>17 cells<sup>140,144</sup>. The proliferation defect in B cells is caused by a cell-cycle arrest within the G1 phase, as described for NF- $\kappa$ B1-deficient B cells<sup>140,141</sup>. Furthermore, cRel-deficient B cells display an impaired antibody production<sup>140</sup>. To investigate if the reduced frequencies of B220<sup>+</sup> B cells in I $\kappa$ B<sub>NS</sub>-deficient mice arise from an impaired apoptosis, the knock down of I $\kappa$ B<sub>NS</sub> was conducted in the B cell line A20 by lentiviral transduction. For this, lentiviral particles with I $\kappa$ B<sub>NS</sub>-targeting shRNA were introduced into A20 cells by using cell spinning. The A20 cells were analysed by Western blot to assess the efficiency of the knock down. To knock down I $\kappa$ B<sub>NS</sub> four sh-RNA were used ( sh1-, sh2-, sh3- or sh4-RNA). Compared to wildtype A20 cells only the usage of the sh1-RNA induced a knock down of I $\kappa$ B<sub>NS</sub> (data not shown). Therefore, these cells were used for the generation of single cell cultures, which resulted in seven clones (sh1-1 to sh1-7). As a control, three clones transduced with scramble (sc) shRNA (sc-1 to sc-3) were generated. Western blot analysis of these cell clones confirmed a reduced expression of I $\kappa$ B<sub>NS</sub> within the four clones sh1-4 to sh1-7 (Figure 8).

**Figure 8: A20 clone cultures transduction with sh1-RNA exhibit a knock down of I $\kappa$ B<sub>NS</sub>.** A20 cells were transfected with scramble control (sc) shRNA or sh1-RNA targeting I $\kappa$ B<sub>NS</sub>. Transduced A20 cells were used to generate single cell cultures (sh1-1 to sh1-7, sc-1 to sc-3). The knock down efficiency of I $\kappa$ B<sub>NS</sub> cultures was analysed by Western blotting using I $\kappa$ B<sub>NS</sub> antibody. The expression of  $\beta$ -actin was analysed to ensure equal loading.

As described above, the deficiency of NF- $\kappa$ B1 cause a enhanced mitogen-induced apoptosis<sup>141</sup>. To assay the sensitivity of the B cell line A20 to CD95-mediated apoptosis, A20 wildtype cells were stimulated using Flag-tagged CD95 ligand (CD95L) in presence or absence of Flag antibodies for 8 and 24 hours (Figure 9). Crosslinking of Flag-tagged

CD95L by addition of Flag antibodies increased the sensitivity to CD95L-induced apoptosis. DNA-fragmentation measurement showed a CD95L-induced apoptosis sensitivity in A20 cells even at low CD95L concentrations with increasing apoptosis sensitivity with higher concentrations of CD95L. The lowest CD95L concentration in addition with Flag antibodies induced considerable apoptosis. This high apoptosis sensitivity stayed constant over time and with increasing CD95L concentrations (Figure 9).

**Figure 9: I $\kappa$ B<sub>NS</sub> wildtype A20 cells are sensitive to CD95-mediated apoptosis.** I $\kappa$ B<sub>NS</sub> wildtype A20 cells were left untreated or stimulated for 8 h or 24 h with CD95L in the presence or absence of 1  $\mu$ g/ml Flag-antibody. The amount of apoptotic cells was quantified by sub-G1 DNA level content. Error bars display the s.e.m. of two measurements.

Moreover, the CD95L-mediated apoptosis sensitivity was quantified in the A20 clone cultures containing the I $\kappa$ B<sub>NS</sub> knock down (Figure 10). The A20 clones sh1-6 and sh1-7 were not sensitive to CD95L-mediated apoptosis in as high extent as the wildtype cells (Figure 10). However, the reduced sensitivity of the clone sh1-6 was overcome by high concentrations of CD95L and the addition of anti-Flag (Figure 10). The transduced scramble cells were also less sensitive to CD95L in comparison to A20 wildtype cells. Furthermore, the two clones sh1-4 and sh1-5 were as sensitive to apoptosis induction as the A20 wildtype cells (Figure 10). Taken together, although the knock down of I $\kappa$ B<sub>NS</sub> induced a reduced sensitivity to death receptor-induced apoptosis in some A20 clones, this is not a general effect and in total there is only a mild reduction. Hence, an increased apoptosis sensitivity upon the knock down of I $\kappa$ B<sub>NS</sub> in B cells is no explanation of the reduction of B220<sup>+</sup> B cells. Consequently, further analysis are necessary to identify the function of I $\kappa$ B<sub>NS</sub> in B cells as well as potential B cell specific target genes of I $\kappa$ B<sub>NS</sub>.

**Figure 10: Apoptosis sensitivity of wildtype A20 cells or A20 cells stably transduced with IκB<sub>NS</sub> targeting sh1-RNA.** A20 cells (sh1-4 to sh1-7 sh1-RNA transduced, sc-1 to sc-3 scramble controls) were left untreated or stimulated for 13 h with CD95L in the presence or absence of 1 μg/ml Flag antibodies. The amount of apoptotic cells was determined by flow cytometry by the quantification of the sub-G1 DNA content. Error bars display the s.e.m. of two measurements.

### 3.1.2 IκB<sub>NS</sub> is not crucial for the activation of CD4<sup>+</sup> T cells

Previous studies demonstrated that IκB<sub>NS</sub> expression is induced upon TCR-triggering<sup>127,128,134</sup>. It is not known, whether the deficiency of IκB<sub>NS</sub> affects the TCR-triggered activation of CD4<sup>+</sup> T cells. To clarify this questions, expanded CD4<sup>+</sup> T cells were activated and the phosphorylation of proteins at tyrosine residues, Akt and the MAP-kinases Erk and p38 as well as the expression of the IκB proteins IκB<sub>NS</sub> and IκBα and the NF-κB family members cRel, NF-κB1, NF-κB2, p65 and RelB was monitored (Figure 11 and Figure 12).

**Figure 11:  $I\kappa B_{NS}$  deficiency did not affect the activation of expanded  $CD4^+$  T cells.** Isolated  $CD4^+CD25^-$  T cells from  $I\kappa B_{NS}^{+/+}$  and  $I\kappa B_{NS}^{-/-}$  mice were expanded. On day 7, cells were left untreated or stimulated with anti-CD3 plus anti-CD28 for the indicated time points. As controls, cells were stimulated with PMA/ ionomycin for 2 hours. The activation was analysed by Western blotting using the indicated phospho-antibodies to tyrosine (**A**), AKT as well as the MAP-kinases Erk and p38 (**B**). The expression of the MAP-kinases (Erk and p38) (**B**) were analysed by Western blotting. Analysis of  $\beta$ -actin expression ensured equal loading. The Western blots shown are representative for three independent experiments.

Upon activation of the TCR via  $\alpha CD3/\alpha CD28$ , wildtype and  $I\kappa B_{NS}$ -deficient cells displayed an equal activation pattern. The phosphorylation of tyrosine residues was similar between  $I\kappa B_{NS}$ -deficient and wildtype cells (Figure 11A). In both genotypes, the phosphorylation of Erk and Akt started already after 15 minutes and decreased after 4 hours of stimulation (Figure 11B). The expression of the p44 isoform of Erk remained constant in the course of stimulation whereas the p42 isoform decreased after 1 hour of activation in both, wildtype and  $I\kappa B_{NS}$ -deficient cells (Figure 11B). A constitutive phosphorylation of p38 was detected in both genotypes, which increased at 2 and 4 hours of  $\alpha CD3/\alpha CD28$  stimulation (Figure 11B). The expression of p38 was consistent in both, wildtype and  $I\kappa B_{NS}$ -deficient cells with a mild decrease to 4 hours. The activation of NF- $\kappa B$  was analysed by  $I\kappa B\alpha$  phosphorylation and degradation.  $I\kappa B\alpha$  was equally phosphorylated and the  $\alpha CD3/\alpha CD28$  stimulation induced an comparable degradation of  $I\kappa B\alpha$  in both genotypes (Figure 12A). After 30 minutes, the  $I\kappa B_{NS}$  expression was induced upon  $\alpha CD3/\alpha CD28$  activation of wildtype cells, as described in the literature (Figure 12A) <sup>127,128</sup>. The  $\alpha CD3/\alpha CD28$  kinetic showed an equal expression profile of the NF- $\kappa B$  subunits cRel, p65, RelB, NF- $\kappa B1$  and NF- $\kappa B2$  in both

genotypes (Figure 12B-C). Taken together, the proximal TCR signalling as well as the T cell activation is not affected by the deficiency of  $I\kappa B_{NS}$ .

**Figure 12: Similar expression of  $I\kappa B\alpha$  and NF- $\kappa B$  subunits in expanded  $CD4^+$   $I\kappa B_{NS}$ -deficient and wildtype T cells.**  $CD4^+CD25^-$  T cells from  $I\kappa B_{NS}^{+/+}$  and  $I\kappa B_{NS}^{-/-}$  mice were isolated and expanded for 7 days. Cells were left untreated or stimulated with anti-CD3 plus anti-CD28 for up to 4 hours. As control, cells were stimulated with PMA/ ionomycin for 2 hours. The activation of  $I\kappa B\alpha$  was analysed by Western blotting by using  $I\kappa B\alpha$  phospho-antibodies (A). The expression of the  $I\kappa B$ -proteins  $I\kappa B_{NS}$  and  $I\kappa B\alpha$  (A) and the NF- $\kappa B$  family members cRel, p65, RelB (B) as well as NF- $\kappa B1$  and NF- $\kappa B2$  (C) is shown. Equal loading was ensured by the analysis of  $\beta$ -actin expression. The shown Western blots are representative for three independent experiments.

### 3.1.3 Both $I\kappa B_{NS}$ forms (35 and 70 kDa) are stable to denaturation by urea

$I\kappa B_{NS}$  is described as a 35 kDa protein<sup>127</sup>. In addition to the 35 kDa isoform Schuster *et al.* showed two, so far undescribed 70 kDa isoforms, which appear upon activation of cells, almost simultaneously to the 35 kDa isoform. Furthermore, the 70 kDa isoforms were detected in the nucleus but not in the cytoplasm of stimulated conventional T cells (Tcon)<sup>134</sup>.

Consistent with the report by Schuster *et al.*<sup>134</sup>, the two 70 kDa isoforms of  $I\kappa B_{NS}$  were detected by Western blot (Figure 8 and Figure 12). The 70 kDa isoforms were observed in

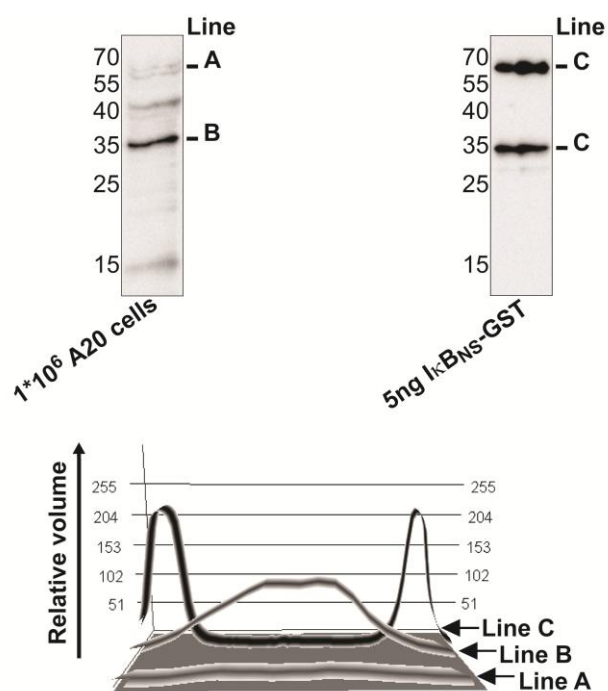

the B cell line A20 (Figure 8) as well as in primary T cells (Figure 12) in a stimulation-dependent manner, but was not detectable in I $\kappa$ B<sub>NS</sub>-deficient (Figure 12) cells. Additionally, diverse antibodies including polyclonal sera of four different immunised rabbits and a mouse IgG2b monoclonal antibody were used to detect the expression of I $\kappa$ B<sub>NS</sub>. All antibodies were able to recognise the 70 kDa isoforms (shown for instance in Figure 15). The double molecular weight of the new isoform of I $\kappa$ B<sub>NS</sub> might be a sign of formation of SDS-stable homodimers of I $\kappa$ B<sub>NS</sub>, which stays stable in SDS-PAGE. To identify the nature of the 70 kDa isoforms, different concentrations of an A20 whole cell lysate were analysed by SDS-PAGE with or without 6 M urea, which destroys hydrogen bonds. SDS- and Urea-PAGE were followed by Western blot analysis. The 70 kDa isoform of I $\kappa$ B<sub>NS</sub> was detected in both SDS-PAGE as well as Urea-PAGE, suggesting posttranslational modification as the origin of the 70 kDa I $\kappa$ B<sub>NS</sub> form (Figure 13).

**Figure 13: The 70 kDa I $\kappa$ B<sub>NS</sub> protein is a urea-stable form.** A20 cell lysates were loaded to a SDS-polyacrylamide gel or a SDS- polyacrylamide gel containing 6 M urea. Lysates were analysed by Western blotting.  $\beta$ -actin and tubulin served as loading controls.

For further characterisation of the 70 kDa isoform of I $\kappa$ B<sub>NS</sub> additional experiments were done to enrich and purify the 70 kDa protein for later mass spectrometry analysis. This is important to reduce problems due to highly abundant proteins. First, the amount of I $\kappa$ B<sub>NS</sub> from  $1 \cdot 10^6$  A20 cells was analysed by Western blotting. Therefore, the lysate of  $1 \cdot 10^6$  A20 cells as well as 5 ng of recombinant GST-tagged I $\kappa$ B<sub>NS</sub> protein were loaded onto SDS-PAGE, I $\kappa$ B<sub>NS</sub> was detected by Western blot (Figure 14, upper panel) and quantified by the program BIO-1D from Peqlab (Figure 14, lower panel). The calculation resulted in a quantity of 1.4 ng per  $1 \cdot 10^6$  cells for the 35 kDa protein. For the 70 kDa protein an amount of 0.4 ng was calculated. Hence, for further experiments at least  $1 \cdot 10^6$  A20 cells were used.

**Figure 14: Calculation of the I $\kappa$ B<sub>NS</sub> protein amount from A20 cells.** The cell lysate of  $1 \times 10^6$  A20 cells and 5 ng recombinant GST-tagged I $\kappa$ B<sub>NS</sub> protein were loaded on an SDS-PAGE gel and analysed by Western blotting (upper panel). The amount of I $\kappa$ B<sub>NS</sub> from  $1 \times 10^6$  A20 cells was calculated using the program BIO-1D (Peqlab, lower panel).

On the one hand, I $\kappa$ B<sub>NS</sub> was immunoprecipitated via protein A sepharose beads (Figure 15) and on the other hand by an affinity column (Figure 16) to enrich and purify the two I $\kappa$ B<sub>NS</sub> proteins from A20 cell lysate. For the immunoprecipitation of I $\kappa$ B<sub>NS</sub> from the lysate of  $1 \times 10^6$  A20 cells using protein A sepharose beads, two monoclonal murine antibodies (Figure 15A) as well as a polyclonal rabbit I $\kappa$ B<sub>NS</sub> antibody (Figure 15B+C) were tested. The immunoprecipitations using the murine I $\kappa$ B<sub>NS</sub> antibodies were efficient enough to enrich the 35 kDa protein, but gave no evidence in terms of the 70 kDa I $\kappa$ B<sub>NS</sub>, because of unspecific protein bands at the same molecular weight (Figure 15A). For the following immunoprecipitations the number of A20 cells was increased to  $2 \times 10^7$  cells and rabbit I $\kappa$ B<sub>NS</sub> antibodies were used. Only one unspecific band at 55 kDa was detected (heavy chain of antibody) in Western blot analysis (Figure 15B) and upon Coomassie Brilliant Blue staining (Figure 15C) using the rabbit I $\kappa$ B<sub>NS</sub> antibodies. The immunoprecipitation of I $\kappa$ B<sub>NS</sub> was successful with both rabbit antibodies. In comparison to the murine antibody, the rabbit antibody was the better choice for the immunoprecipitation of I $\kappa$ B<sub>NS</sub>, since it gave a better purified elution fraction without any  $\beta$ -actin contamination (Figure 15B). Finally, the immunoprecipitation with rabbit I $\kappa$ B<sub>NS</sub> antibodies resulted in a protein band stainable with Coomassie Brilliant Blue (Figure 15C).

**Figure 15: Immunoprecipitation of I $\kappa$ B<sub>NS</sub> via protein A sepharose beads.** Monoclonal murine (A) or polyclonal rabbit (B-C) I $\kappa$ B<sub>NS</sub> antibodies (Ab) were bound to protein A sepharose beads and total cell lysates from A20 cells were added to the beads (in (A)  $1 \times 10^6$  cells, in (B-C)  $2 \times 10^7$  cells). After the incubation of the beads with the protein lysate a minor part of the supernatant was collected for analysis (supernatant). Three washing steps were performed followed by an elution step. The eluate was analysed by SDS-PAGE followed by Western blot analysis (A-B), using antibodies directed to I $\kappa$ B<sub>NS</sub> and  $\beta$ -actin. Furthermore, the eluate was analysed via Coomassie Brilliant Blue staining, black boxes indicate the predicted protein bands of I $\kappa$ B<sub>NS</sub> and arrows show the heavy and light chain band of the rabbit I $\kappa$ B<sub>NS</sub> antibody (C).

To obtain adequate protein amounts for mass spectrometry analysis the amount of cell lysate was increased and an affinity column was used for immunoprecipitation. Hence, the lysate of  $1.5 \times 10^8$  A20 cells was added to columns coupled with rabbit I $\kappa$ B<sub>NS</sub> or rabbit IgG antibodies, respectively (Figure 16). After five washing steps (flow through), two elution steps were performed. No binding of I $\kappa$ B<sub>NS</sub> to the rabbit IgG coupled column, but specific binding of I $\kappa$ B<sub>NS</sub> to the I $\kappa$ B<sub>NS</sub> antibody coupled column could be detected by Western Blotting within the second elution (Figure 16A). Furthermore, no contamination with  $\beta$ -actin was discovered. In addition, the two elution fractions were analysed by Coomassie Brilliant Blue staining showing two protein bands at the predicted molecular weight of I $\kappa$ B<sub>NS</sub>. Additionally, one band for the heavy as well as the light chain of the I $\kappa$ B<sub>NS</sub> antibody was detected (Figure 16B). Unexpectedly, the predicted protein bands were not only detectable in the elution of the I $\kappa$ B<sub>NS</sub> antibody-coupled column, but also within the elution of the rabbit IgG control column, indicating an unspecific contamination with random proteins either only in the control or in both columns. Consequently, prior to mass

spectrometry analysis further experiments are necessary to optimise the enrichment and purification of the I $\kappa$ B<sub>NS</sub> isoforms.

**Figure 16: Affinity purification of I $\kappa$ B<sub>NS</sub> via a mini column.** After the binding of antibodies directed to I $\kappa$ B<sub>NS</sub> or rabbit IgG to a MicroLink™ Protein Coupling column, the cell lysate of  $1.5 \times 10^8$  A20 cells was added to the column. Five washing steps and two elution steps were performed. The flow through of the first (1. flow through) and the last washing step (5. flow through) and the eluate (1. elution and 2. elution) of each column was analysed by SDS page followed by Western blot analysis (**A**) using antibodies directed against I $\kappa$ B<sub>NS</sub> and  $\beta$ -actin. Furthermore, the eluate was analysed via Coomassie Brilliant Blue staining, arrows shown from top to bottom: presumed 70 kDa I $\kappa$ B<sub>NS</sub>, heavy chain band of the rabbit I $\kappa$ B<sub>NS</sub> antibody, presumed 35 kDa I $\kappa$ B<sub>NS</sub> and light chain band of the rabbit I $\kappa$ B<sub>NS</sub> antibody (**B**).

## 3.2 The role of I $\kappa$ B<sub>NS</sub> in T<sub>H</sub>17 cell development

### 3.2.1 Setup of an efficient *in vitro* polarisation of T<sub>H</sub>17 cells

In the literature numerous protocols for the *in vitro* polarisation of T<sub>H</sub>17 are reported<sup>40,56,145,146</sup>. The common ground of these reports is the necessity of IL6 and TGF $\beta$ <sup>40,56,145,146</sup>. In addition, several other cytokines like IL1 $\beta$ , IL21 and IL23 were described to play an important role in initiation, stabilisation and/ or maintenance of T<sub>H</sub>17 cells<sup>44,64,65,146,147</sup>.

Before starting with the *in vitro* polarisation of T<sub>H</sub>17 cells, the genotype of mice was determined using biopsies of mouse tails (Figure 17). For the genotyping three primers were used, two I $\kappa$ B<sub>NS</sub> primer and one primer specific to the neomycin cassette, which was inserted while the generation of the I $\kappa$ B<sub>NS</sub> knockout. I $\kappa$ B<sub>NS</sub>-deficient mice were distinguished from wildtype mice by the shorter DNA fragment size (Figure 17), induced via target gene disruption by deletion of 4.8kb from the I $\kappa$ B<sub>NS</sub> gene locus<sup>128</sup>. By this way, wildtype and I $\kappa$ B<sub>NS</sub>-deficient mice were identified and used for further experiments.

**Figure 17: Genotyping of I $\kappa$ B<sub>NS</sub> offspring.** Tail biopsies from I $\kappa$ B<sub>NS</sub> mice were lysed and DNA was used to genotype wildtype (I $\kappa$ B<sub>NS</sub><sup>+/+</sup>), heterozygous (I $\kappa$ B<sub>NS</sub><sup>+/-</sup>) and I $\kappa$ B<sub>NS</sub>-deficient (I $\kappa$ B<sub>NS</sub><sup>-/-</sup>) mice by polymerase chain reaction. The particular genotype was determined by DNA fragment size after agarose gel electrophoresis.

To identify the best working combination of cytokines and additives for the *in vitro* T<sub>H</sub>17 cell polarisation, naïve T cells (CD4<sup>+</sup>CD62L<sup>+</sup>CD25<sup>-</sup>) were isolated from spleen, peripheral lymph nodes (pLN) and mesenteric lymph nodes (mLN) of I $\kappa$ B<sub>NS</sub>-deficient and wildtype mice (Figure 18). As shown in the upper panel of Figure 18 the cell mixture of spleen, pLN and mLN cells contained only a minor fraction of the required cells. The reanalysis of the isolated cell population revealed a purity of 95 to 98% of CD4<sup>+</sup>CD62L<sup>+</sup>CD25<sup>-</sup> naïve T cells (Figure 18, lower panel).

**Figure 18: The isolation of naïve T cells by flow cytometry results in a highly pure population.** Spleen, pLN and mLN were isolated from  $I\kappa B_{NS}^{+/+}$  and  $I\kappa B_{NS}^{-/-}$  mice. Cells were stained with antibodies directed to CD4, CD25 and CD62L. Flow cytometric cell sorting was used to isolate  $CD4^+CD62L^{high}CD25^-$  naïve T cells. The upper panel shows dot blots of non-sorted primary cells and the lower panel a re-analysis of isolated naïve T cells from wildtype and  $I\kappa B_{NS}^{-/-}$  deficient mice.

To determine the best working medium for  $T_H17$  cells polarisation, the first experiment was performed using different media (Figure 19A). Furthermore, various concentrations of CD3 antibodies ( $\alpha CD3$ , Figure 19B) as well as medium additives like  $TGF\beta$  and IL6 (Figure 19D) were tested. In addition, different plate sizes (Figure 19B) and plate suppliers (Figure 19C) were used. All experiments were performed by using naïve wildtype T cells and the  $T_H17$ -basic condition (containing  $\alpha CD3$ ,  $\alpha CD28$ ,  $\alpha IL4$ ,  $\alpha IFN\gamma$ ,  $TGF\beta$ , IL6). First, both media IMDM or RPMI as well as combinations of FCS (standard or tetracyclin-free), sodium pyruvate and non-essential amino acids (NEAA) were tested (Figure 19A). The cell number stayed stable in all five tested combinations. However, the medium containing RPMI plus FCS standard, sodium pyruvate and NEAA gave a mildly increased cell number after  $T_H17$  polarisation, hence it was used for further experiments. The  $T_H17$  polarisation using  $2 \mu g/ml$   $\alpha CD3$  in 24 well plates (Figure 19B)

resulted in the best proliferation. Furthermore, testing different 24 well plate suppliers showed the highest cell number using the plates from nunc, starlab, PAA, Millipore and CellStar. In following experiments the 24 well plates from nunc were used, because of the low variability of the cell number within the two experiments. The *in vitro* polarisation of  $T_H17$  cells depended on the concentration of TGF $\beta$  and IL6 and the lowest concentration of both cytokines resulted in an increased cell proliferation (Figure 19D). Accordingly, the  $T_H17$  polarisation of further experiments were performed in 24 well plates from nunc with plate-bound 2  $\mu\text{g/ml}$   $\alpha\text{CD3}$  using RPMI medium containing FCS standard, sodium pyruvate, NEAA, 0.5 ng/ml TGF $\beta$  and 20 ng/ml IL6.

**Figure 19: Determination of the most suitable condition for *in vitro*  $T_H17$  polarisation.** Naïve T cells were isolated by flow cytometry.  $0.5 \times 10^6$  (A+C) or  $1 \times 10^6$  (B+D) cells were cultured for 5 days under  $T_H17$ -polarising conditions. On day 5, the absolute cell number was determined. For the polarisation of  $T_H17$  cells different medium additives (A), concentrations of  $\alpha\text{CD3}$  and plate sizes (B), plates of various suppliers (C) and concentrations of TGF $\beta$  and IL6 (D) were tested. Data represent one experiment (A-B) or are pooled from two independent experiments (C-D).

**Figure 20: Test of different additive combinations for T<sub>H</sub>17 cell polarisation.** Naïve T cells were isolated and  $1 \times 10^6$  cells were cultured for 5 days under different T<sub>H</sub>17-polarising conditions. At day 5, the cells were stimulated with PMA/ ionomycin (4 h) and BrefeldinA (2 h). The total cell number was determined (A) and the frequencies of IFN<sub>γ</sub><sup>+</sup> (B) or IL17A<sup>+</sup> (C) cells were measured by flow cytometry (upper panel of B and C) and the number of IFN<sub>γ</sub><sup>+</sup> or IL17A<sup>+</sup> cells was calculated (lower panel of B and C). Error bars display the s.e.m. and are representative for five independent experiments. Statistical analyses were performed by two-tailed Mann-Whitney U test; (\*)  $p < 0.05$ , (\*\*)  $p < 0.01$ .

To identify a promising cytokine combination for the *in vitro* T<sub>H</sub>17 polarisation, naïve T cells were cultured under T<sub>H</sub>17-basic condition (containing  $\alpha$ CD3,  $\alpha$ CD28,  $\alpha$ IL4,  $\alpha$ IFN<sub>γ</sub>, TGF $\beta$ , IL6) alone or in combination with IL1 $\beta$  (T<sub>H</sub>17-IL1 $\beta$ ), IL21 (T<sub>H</sub>17-IL21), IL23 (T<sub>H</sub>17-IL23) or IL21 plus IL23 (T<sub>H</sub>17-IL21/23) (Figure 20). Additionally, cells were cultured under T<sub>H</sub>1 and non-priming (T<sub>H</sub>0) conditions (Figure 20). On day 5, a reduced number of IκB<sub>NS</sub>-deficient T cells compared to wildtype cells was determined in almost all conditions, except in the T<sub>H</sub>17-IL1 $\beta$  condition (Figure 20A). The frequency of IL17A-producing cells showed an increased in IκB<sub>NS</sub>-deficient T<sub>H</sub>17-basic and T<sub>H</sub>17-IL21 polarised cells compared to wildtype cells (Figure 20C upper panel). Nevertheless, the number of IL17A<sup>+</sup> cells was comparable among T<sub>H</sub>17-basic and T<sub>H</sub>17-IL21 polarised IκB<sub>NS</sub>-deficient and wildtype T cells (Figure 20C lower panel). Additionally, while the frequency of T<sub>H</sub>17-IL23 polarised IL17A<sup>+</sup> cells was similar in both genotypes, the number

of IL17A<sup>+</sup> cells was significantly reduced in IκB<sub>NS</sub>-deficient cells (Figure 20C). The analysis of T<sub>H</sub>17-IL21/23 and T<sub>H</sub>17-IL1β polarised cells showed an equal frequency and cell number of IL17A<sup>+</sup> IκB<sub>NS</sub>-deficient compared to wildtype T cells (Figure 20C). Furthermore, the determination of the frequency and the cell number of IFNγ<sup>+</sup> cells showed a reduced polarisation within the IFNγ<sup>+</sup> T<sub>H</sub>0 and T<sub>H</sub>1 IκB<sub>NS</sub>-deficient T cells compared to wildtype T cells (Figure 20B). Thus, IκB<sub>NS</sub>-deficient cells indicated a affected proliferation upon T<sub>H</sub>17-polarisation.

The five T<sub>H</sub>17 polarising conditions illustrated variable effects of IκB<sub>NS</sub> deficiency. Furthermore, the frequency of IL17A<sup>+</sup> cells was between 1.5 and 5 %, hence a majority of cells were non-polarised (Figure 20). To determine the best time point regarding number and frequency of IL17A<sup>+</sup> cells a differentiation kinetic was performed (Figure 21). The cell number mildly dropped within the first 24 h, then increased until day 5 (Figure 21A). The frequency of IL17A<sup>+</sup> cells was mildly increased at the first day followed by a peak at day 2 (Figure 21B). From day 2 to day 4 the frequency of IL17A<sup>+</sup> cells stayed stable. Furthermore, the frequency of IL17A<sup>+</sup> dropped by half at day 5 (Figure 21B). Hence, the following T<sub>H</sub>17 polarisation experiments were performed over a period of 4 days.

**Figure 21: Differentiation kinetics of *in vitro* cultured T<sub>H</sub>17 cell.** 1\*10<sup>6</sup> isolated naïve T cells were cultured for up to 5 days under T<sub>H</sub>17-polarising conditions (T<sub>H</sub>17-IL23 condition). The cells were stimulated for 4 h with PMA/ ionomycin together with Brefeldin A for the last 2 h and stained with antibodies directed to IL17A. The number of cells was counted (A) and the frequency of IL17A<sup>+</sup> cells was measured by flow cytometry (B). Error bars display the s.e.m. and are representative for three independent experiments.

**Figure 22: Modification of T<sub>H</sub>17 polarisation conditions resulted in increased frequency of IL17<sup>+</sup> cells.** Naïve T cells were isolated by flow cytometry and  $1 \times 10^6$  cells were cultured for 4 or 6 days under T<sub>H</sub>17- polarising conditions. The cells were stimulated with PMA/ ionomycin (P/I, 4 h) together with Brefeldin A for the last 2 h. The frequency of IL17A<sup>+</sup> cells was measured by flow cytometry. Data are representative for two independent experiments. The s.e.m. is shown by error bars.

At that point, another T<sub>H</sub>17 differentiation protocol, published by Carlson *et al.*, with an alternative cytokine combination was tested<sup>148</sup>. The new cytokine-antibody mixture, in the following called T<sub>H</sub>17 condition, included  $\alpha$ CD3 (3  $\mu$ g/ml),  $\alpha$ CD28 (5  $\mu$ g/ml),  $\alpha$ IL2 (10  $\mu$ g/ml),  $\alpha$ IFN $\gamma$  (10  $\mu$ g/ml), TGF $\beta$  (2 ng/ml), IL6 (30 ng/ml), IL1 $\beta$  (10 ng/ml) and TNF $\alpha$  (20 ng/ml). In contrast to previous T<sub>H</sub>17 conditions, higher concentrations of  $\alpha$ CD3 (3  $\mu$ g/ml),  $\alpha$ CD28 (5  $\mu$ g/ml), TGF $\beta$  (2 ng/ml) and IL6 (30 ng/ml) were used. In the prior T<sub>H</sub>17 polarisation experiments  $\alpha$ IL4 was used to inhibit the polarisation into T<sub>H</sub>2 cells. Instead, the new protocol included  $\alpha$ IL2 to inhibit the IL2 induced suppression of T<sub>H</sub>17 cell polarisation<sup>41,43</sup>. Furthermore, in contrast to previous T<sub>H</sub>17 polarisation experiments TNF $\alpha$  was used as an additional cytokine. Prior T<sub>H</sub>17 polarisation protocols resulted in an output of about 5% IL17A<sup>+</sup> cells. The new tested T<sub>H</sub>17 polarisation protocol increased the frequency of IL17A<sup>+</sup> cells to roundabout 60% (Figure 22). For this reason, the following experiments were performed with the new T<sub>H</sub>17 polarisation conditions.

### 3.2.2 I $\kappa$ B<sub>NS</sub> drives the differentiation of both T<sub>H</sub>17 and T<sub>H</sub>1 cells.

The transcription factor NF- $\kappa$ B plays a key role in the immune system<sup>12,93,149</sup>. For instance, the proliferation and effector function of T cells depends on the T cell receptor (TCR)-triggered NF- $\kappa$ B-mediated activation of the cell<sup>12,93,149</sup>. The pathway leading from TCR and NF- $\kappa$ B activation to gene transcription is regulated by multiple components including the I $\kappa$ B protein family<sup>123,128,131,150</sup>.

**Figure 23: IκB<sub>NS</sub> is expressed in *in vitro* differentiated activated T cells.** Naïve T cells were isolated by flow cytometry and cultured for 4 days under T<sub>H</sub>1-, T<sub>H</sub>17- or non-polarising (T<sub>H</sub>0) conditions (A-C). The cells were left untreated or stimulated with PMA/ ionomycin (P/I, 4 h) and the induction of IκB<sub>NS</sub> was measured by PCR (A), qPCR (B) or Western blotting (C). Data shown in A and C are representative for at least three independent experiments. Error bars display the s.e.m. of four experiments (B). Statistical analyses were performed by two-tailed Mann-Whitney U test; (\*) p<0.05.

T<sub>H</sub>1 and T<sub>H</sub>17 cells are important in host protection to a variety of intracellular (T<sub>H</sub>1) and extracellular (T<sub>H</sub>17) pathogens. To identify whether the IκB protein family member IκB<sub>NS</sub> is expressed in T<sub>H</sub>1 and T<sub>H</sub>17 cells, the expression of IκB<sub>NS</sub> under T<sub>H</sub>1-, T<sub>H</sub>17- and non-polarising (T<sub>H</sub>0) conditions was analysed. The expression of IκB<sub>NS</sub> was determined on the mRNA level by conventional RT-PCR (Figure 23A) as well as qPCR (Figure 23B). Consistent with published data<sup>127,134</sup>, the IκB<sub>NS</sub> mRNA expression was induced upon T cell activation (Figure 23A and B). Additionally, the analysis by RT-PCR and qPCR displayed the highest expression level of IκB<sub>NS</sub> mRNA in activated non-polarised (T<sub>H</sub>0) cells (Figure 23A+B). RT-PCR analysis revealed a mildly reduced IκB<sub>NS</sub> expression in T<sub>H</sub>1 compared to T<sub>H</sub>17 cells (Figure 23A), whereas T<sub>H</sub>1 and T<sub>H</sub>17 polarised cells showed an equal fold induction of IκB<sub>NS</sub> mRNA analysed by qPCR (Figure 23B). In total, T<sub>H</sub>0, T<sub>H</sub>1 and T<sub>H</sub>17 showed a similar IκB<sub>NS</sub> mRNA expression. Furthermore, the expression of IκB<sub>NS</sub> on the protein level (Figure 23C) was analysed. Again, IκB<sub>NS</sub> expression could be detected after the activation of T cells with PMA/ ionomycin. The protein expression of IκB<sub>NS</sub> was equal in T<sub>H</sub>0 and T<sub>H</sub>17 polarised cells. In contrast to the mRNA data, T<sub>H</sub>1 polarised cells showed the highest IκB<sub>NS</sub> protein level, which indicates diversified translational and/ or post-transcriptional modulation of the IκB<sub>NS</sub> expression in the

different T cell subsets (Figure 23C). Taken together, the activation dependent expression of  $I\kappa B_{NS}$  directs the development of  $T_H1$  and  $T_H17$  cells, however its expression is not restricted to a single T helper subset.

**Figure 24: Tbet and RORγt are equally expressed in  $I\kappa B_{NS}^{+/+}$  and  $I\kappa B_{NS}^{-/-}$  T cells.** Isolated naïve T cells were cultured for 4 days under  $T_H1$ -,  $T_H17$ - or non-polarising ( $T_H0$ ) conditions. Subsequently, T cells were left untreated or stimulated with PMA/ ionomycin (P/I, 4h). The expression of RORγt (A+B) and Tbet (A+C) was analysed by RT-PCR (A) and qPCR (B+C). The qPCR data were normalised to non stimulated  $T_H0$  wildtype cells and the fold change was calculated. Error bars display the s.e.m. of three independent experiments.

Naïve T cells were cultured under  $T_H0$ -,  $T_H1$ - and  $T_H17$ -priming conditions, to analyse the effect of the  $I\kappa B_{NS}$  deficiency on the polarisation of T cell subsets. The mRNA expression of RORγt and Tbet was determined by RT-PCR (Figure 24A) as well as qPCR (Figure 24B-C). In RT-PCR analysis, the master transcription factor of  $T_H17$  cells, RORγt was highly expressed in non-stimulated as well as stimulated  $T_H17$  cells with a comparable expression level in both genotypes (Figure 24A). On the contrary, the qPCR analysis showed a mild increase of RORγt in  $I\kappa B_{NS}$ -deficient  $T_H17$  cells (Figure 24B). The master transcription factor of  $T_H1$  cells, Tbet was equally expressed in  $I\kappa B_{NS}$ -deficient and wildtype  $T_H1$  cells (Figure 24A+C). In addition,  $T_H17$  cells did not express Tbet (Figure

24A+C). Taken together, the master transcription factors of the T cell subsets  $T_H1$  and  $T_H17$ , Tbet and ROR $\gamma$ t, exhibited an equal expression pattern comparing wildtype and  $I\kappa B_{NS}$ -deficient cells.

Although the  $I\kappa B_{NS}$  deficiency did not affect the mRNA expression of the master transcription factors of  $T_H1$  and  $T_H17$  cells, the defect can influence the differentiation of T cells as it was shown for  $I\kappa B\zeta$  in  $T_H17$  cell differentiation<sup>121</sup>. To identify if  $I\kappa B_{NS}$  plays an essential role in driving the development of naïve T cells to  $T_H1$  or  $T_H17$  cells, wildtype and  $I\kappa B_{NS}$ -deficient T cells cultured under  $T_H1$  or  $T_H17$  polarising conditions were analysed by flow cytometry (Figure 25). A severely reduced frequency of  $IFN\gamma^+$   $T_H1$  as well as  $IL17A^+$   $T_H17$  cells was monitored in the absence of  $I\kappa B_{NS}$ , whereas the frequency of *in vitro* differentiated  $T_H1$  and  $T_H17$  cells showed a 2-fold reduction in  $I\kappa B_{NS}$ -deficient cells (Figure 25B and C, left panel). Additionally, the number of  $IFN\gamma^+$   $T_H1$  as well as  $IL17A^+$   $T_H17$  cells was reduced in  $I\kappa B_{NS}$ -deficient compared to wildtype cells (Figure 25B and C, right panel).

**Figure 25: Impaired *in vitro* polarisation of  $T_H1$  and  $T_H17$  cells in the absence of  $I\kappa B_{NS}$ .** Isolated naïve T cells were cultured under  $T_H1$  or  $T_H17$ -polarising conditions. On day 4, the cells were stimulated with PMA/ ionomycin (4 h) and BrefeldinA (2 h). The frequencies of  $IFN\gamma^+$  (left panel) and  $IL17A^+$  (right panel) cells were measured by flow cytometry (B). Representative dot plots are shown in (A). The number of  $IFN\gamma^+$  as well as  $IL17A^+$  cells was calculated (C). Error bars display the s.e.m. and are representative for four independent experiments. Statistical analyses were performed by two-tailed Mann-Whitney U test; n.s.= not significant, (\*)  $p < 0.05$ .

In addition, the effects induced by the  $I\kappa B_{NS}$  deficiency was further analysed by determination of cell numbers over time, to identify the reason for the reduced frequency of *in vitro* polarised  $T_H17$  and  $T_H1$  cells (Figure 26). The frequency (Figure 26A) as well as the cell number (Figure 26B) of  $IFN\gamma^+$   $T_H1$ -primed as well as  $IL17A^+$   $T_H17$ -primed cells was determined. Already at day 3, an impaired development of  $T_H1$ - and  $T_H17$ -polarised cells was detected upon the deficiency of  $I\kappa B_{NS}$  (Figure 26).

**Figure 26: Division profile analysis of  $I\kappa B_{NS}$  wildtype and knockout T cells indicate a proliferation defect induced by  $I\kappa B_{NS}$ -deficiency.** After the isolation of naïve T cells, cells were cultured under  $T_H1$ - or  $T_H17$ -polarising conditions. From day 3 to 6, some cells were stimulated with PMA/ ionomycin (4 h) and BrefeldinA (2 h). The frequency of  $IFN\gamma^+$  (upper panel) and  $IL17A^+$  (lower panel) cells was measured by flow cytometry (A) During the differentiation, numbers of  $IFN\gamma^+$  (upper panel) and  $IL17A^+$  (lower panel) cells were determined at day 3 to day 6 (B).

**Figure 27: IκB<sub>NS</sub>-deficient T cells display a cell intrinsic proliferation defect *in vitro*.** Naïve T cells were isolated by flow cytometry from CD90.1<sup>+</sup> IκB<sub>NS</sub><sup>+/+</sup> and CD90.2<sup>+</sup> IκB<sub>NS</sub><sup>-/-</sup> mice. Cells were mixed in a ratio of 1:1. After CFSE-labelling T cells were cultured under T<sub>H</sub>1- (middle panel), T<sub>H</sub>17- (lower panel) or non-polarising (T<sub>H</sub>0, upper panel) conditions (A-C). At day 4, stimulated cells were analysed by flow cytometry regarding the CFSE intensity of IFNγ<sup>+</sup> or IL17A<sup>+</sup> cells within the two genotypes. Representative dot plots of IκB<sub>NS</sub><sup>+/+</sup> (CD90.1<sup>+</sup>) and IκB<sub>NS</sub><sup>-/-</sup> (CD90.2<sup>+</sup>) cells (pre-gated to viable cells) are shown in (A). Representative histograms of the CFSE intensity of IFNγ<sup>+</sup> or IL17A<sup>+</sup> cells (pre-gated to CD90.1<sup>+</sup> or CD90.2<sup>+</sup> cells) are shown in (B). Statistical analysis of the calculated division index of wildtype and knockout T cells are shown in (C). Error bars displaying the s.e.m. are representative for four independent experiments and two-tailed Mann-Whitney U test was used; (\*) p<0.05.

To determine whether this effect induced by IκB<sub>NS</sub> deficiency could be compensated by wildtype cells, CFSE stained naïve IκB<sub>NS</sub>-deficient (CD90.2<sup>+</sup>) T cells were cultured in the presence of CFSE stained naïve wildtype (CD90.1<sup>+</sup>) T cells (Figure 27). Once again, the frequency of IκB<sub>NS</sub>-deficient (CD90.2<sup>+</sup>) T<sub>H</sub>1 and T<sub>H</sub>17 as well as T<sub>H</sub>0 cells showed a reduction of 50% compared to wildtype (CD90.1<sup>+</sup>) cells (Figure 27A). The CFSE proliferation profile revealed a T helper cell intrinsic effect due to the fact that wildtype cells undergo more proliferation steps in comparison to IκB<sub>NS</sub>-deficient cells (Figure 27B). Furthermore, the mean number of divisions per cell (division index; including non-divided cells) was calculated from the CFSE profile shown in Figure 27B. Hence, the division index of the co-cultured T cells showed a significant decrease within the IκB<sub>NS</sub>-deficient

T<sub>H</sub>0, T<sub>H</sub>1 and T<sub>H</sub>17 cells confirming the hypothesis of a T helper cell intrinsic proliferation defect (Figure 27C).

### 3.2.3 The loss of I $\kappa$ B<sub>NS</sub> alters the *in vitro* expression of cytokines by T<sub>H</sub>17 cells.

Previous reports revealed that I $\kappa$ B<sub>NS</sub> restricts IL6 and IL12p40 expression in macrophages and dendritic cells, whereas it enhances expression of IL2 and IFN $\gamma$  in T cells<sup>128,129,131</sup>. Due to the effect of I $\kappa$ B<sub>NS</sub> deficiency on T cell proliferation, it was analysed whether T<sub>H</sub>17 cells display impaired cytokine expression upon the loss of I $\kappa$ B<sub>NS</sub>.

Naïve T cells were cultured under T<sub>H</sub>1- and T<sub>H</sub>17-priming conditions, to analyse the effect of the I $\kappa$ B<sub>NS</sub> deficiency on the cytokine expression of T cell subsets. The mRNA expression of IL17A (Figure 28A-B) and IFN $\gamma$  (Figure 28A+D) was determined by RT-PCR (Figure 28A) and qPCR (Figure 28B+D). In addition, the protein expression of IL17A (Figure 28C) and IFN $\gamma$  (Figure 28E) was analysed by the measurement of the mean fluorescence intensity (MFI). In RT-PCR, IL17A expression was increased in non-stimulated I $\kappa$ B<sub>NS</sub>-defective T<sub>H</sub>17 cells compared to wildtype cells (Figure 28A). Furthermore, the analysis by RT-PCR revealed a stimulation-induced expression of IL17A, which was comparable in I $\kappa$ B<sub>NS</sub>-deficient and wildtype T<sub>H</sub>17 cells (Figure 28A). In contrast, qPCR analysis showed a stimulation-induced expression of IL17A in wildtype cells but not in I $\kappa$ B<sub>NS</sub>-deficient T<sub>H</sub>17 cells (Figure 28B). Indeed, in qPCR analysis the IL17A expression was reduced in stimulated I $\kappa$ B<sub>NS</sub>-deficient cells compared to non-stimulated I $\kappa$ B<sub>NS</sub>-deficient as well as wildtype T<sub>H</sub>17 cells (Figure 28B). Consistent with qPCR data, the loss of I $\kappa$ B<sub>NS</sub> induced a mild, but not significant, reduction of the IL17A protein expression in T<sub>H</sub>17 cells (Figure 28C). The RNA expression of the T<sub>H</sub>1 effector cytokine, IFN $\gamma$  was induced in T<sub>H</sub>1 cells as well as T<sub>H</sub>0 cells upon cell stimulation (Figure 28A+D). Furthermore, RT-PCR analysis revealed an increased expression of IFN $\gamma$  in I $\kappa$ B<sub>NS</sub>-deficient non-stimulated T<sub>H</sub>1 cells compared to wildtype, but a similar expression upon activation (Figure 28A). In qPCR analysis, IFN $\gamma$  was equally expressed in non-stimulated as well as activated T<sub>H</sub>1 cells of both genotypes (Figure 28D). In contrast, the analysis of the MFI of IFN $\gamma$  uncovered a significant reduction of the protein expression in T<sub>H</sub>1 I $\kappa$ B<sub>NS</sub>-defective cells (Figure 28E). Taken together, qPCR analysis indicated a reduced IL17A expression in I $\kappa$ B<sub>NS</sub>-deficient compared to wildtype T<sub>H</sub>17 cells (Figure 28B). This reduction was confirmed by the analysis of IL17A protein expression (Figure 28C). Furthermore, the RNA of the T<sub>H</sub>1 effector cytokine IFN $\gamma$  is equally expressed in T<sub>H</sub>1

cells comparing both genotypes (Figure 28A+D), but the IFN $\gamma$  protein expression was reduced in I $\kappa$ B<sub>NS</sub>-defective T<sub>H</sub>1 cells (Figure 28E). Altogether, the protein expression on a per cell basis (MFI) was significantly reduced for IFN $\gamma$  but not for IL17A.

**Figure 28: Similar RNA expression of IFN $\gamma$  and IL17F in I $\kappa$ B<sub>NS</sub><sup>+/+</sup> and I $\kappa$ B<sub>NS</sub><sup>-/-</sup> T cells, but reduced protein expression of both cytokines.** After the isolation of naïve T cells by flow cytometry the cells were cultured under T<sub>H</sub>1-, T<sub>H</sub>17- or non-polarising (T<sub>H</sub>0) conditions. On day 4, the expression of IL17A (A-C) and IFN $\gamma$  (A,D-E) was analysed by RT-PCR (A), qPCR (B+D) or flow cytometry (C+E). The RT-PCR data are representative for two independent experiments (A). The qPCR data were normalised to non-stimulated T<sub>H</sub>17 wildtype cells (B) or non-stimulated T<sub>H</sub>0 wildtype cells (D) and the fold change was calculated. Error bars display the s.e.m. of three (B+D) or four (C+E) independent experiments. Statistical analyses were performed by two-tailed Mann-Whitney U test; n.s.= not significant, (\*) p<0.05.

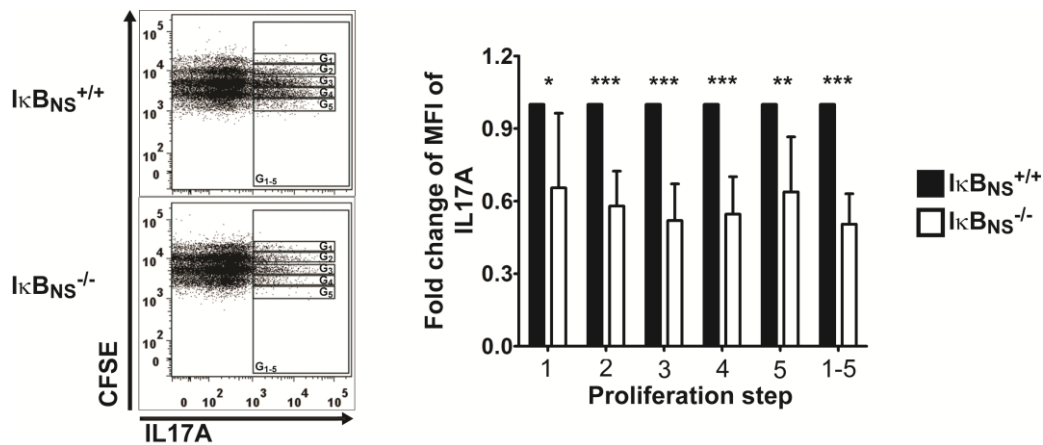

**Figure 29: Reduced IL17A expression in  $I\kappa B_{NS}$ -deficient  $T_H17$ -polarised cells.** Naïve T cells were isolated by flow cytometry from  $I\kappa B_{NS}^{+/+}$  and  $I\kappa B_{NS}^{-/-}$  mice. Naïve wildtype and  $I\kappa B_{NS}$ -deficient T cells were stained either with CFSE or CellTrace™ Violet Proliferation Dye, mixed in a ratio of 1:1 and cultured under  $T_H17$ -polarising conditions. On day 4, cells were stimulated with PMA/ ionomycin (4 h) and BrefeldinA (2 h). IL17A-producing cells were analysed by flow cytometric measurement. In (A)  $I\kappa B_{NS}^{+/+}$  cells were stained with Violet Proliferation dye and  $I\kappa B_{NS}^{-/-}$  cells with CFSE. In (B)  $I\kappa B_{NS}^{+/+}$  cells were stained with CFSE and  $I\kappa B_{NS}^{-/-}$  cells were stained with Violet Proliferation dye.

For further analysis of the reduced expression of IL17A, naïve T cells were stained using a proliferation dye, followed by cultivation of  $I\kappa B_{NS}$ -deficient naïve T cells in the presence of  $I\kappa B_{NS}$  wildtype naïve T cells (Figure 29). To exclude that the proliferation dye-induced effects,  $I\kappa B_{NS}$ -deficient T cells were either stained with CFSE (Figure 29A) or CellTrace™ Violet Proliferation Dye (Figure 29B) and wildtype T cells were stained with the opposite dye. The  $T_H17$  polarisation of naïve T cells indicated a diminished proliferation in  $I\kappa B_{NS}$ -deficient cells (Figure 29). As already shown above, a bit more wildtype cells pass through five divisions compared to  $I\kappa B_{NS}$ -defective cells. Furthermore, a reduced number of naïve  $I\kappa B_{NS}$ -deficient T cells differentiated into IL17A expressing cells compared to wildtype cells. Moreover, apparently each proliferation step of IL17<sup>+</sup>  $I\kappa B_{NS}$ -deficient T cells exhibited a reduced MFI of IL17A (Figure 29). Nevertheless, both proliferation dyes emit in a different colour, therefore a direct side-by-side comparison of  $I\kappa B_{NS}$ -deficient and wildtype cells is impossible. For this reason, CFSE stained  $I\kappa B_{NS}$ -deficient (CD90.2<sup>+</sup>) naïve T cells were polarised together with CFSE stained congenic wildtype (CD90.1<sup>+</sup>) cells (Figure 30). Single proliferation steps were gated in the dot blot (Figure 30, left

panel) and analysed for the MFI of IL17A (Figure 30, right panel). The deficiency of  $I\kappa B_{NS}$  in  $T_H17$  cells induced a severely reduced expression of IL17A compared to wildtype  $T_H17$  cells. This analysis indicated that  $I\kappa B_{NS}$  participates in cytokine expression of  $T_H17$  cells.

**Figure 30:  $I\kappa B_{NS}$  deficiency impairs the expression of IL17A.** Isolated naive  $I\kappa B_{NS}^{+/+}$  ( $CD90.1^+$ ) and  $I\kappa B_{NS}^{-/-}$  ( $CD90.2^+$ ) T cells were mixed in a ratio of 1:1, stained with CFSE and cultured under  $T_H17$ - polarising conditions. On day 4, IL17A expression was analysed by flow cytometry. The mean fluorescence intensity (MFI) of IL17A<sup>+</sup> per each proliferation cycle was analysed. Representative dot plots indicating the MFI of IL17A within five proliferation steps (G1-G5, left panel). The fold change of MFI of IL17A in  $I\kappa B_{NS}^{-/-}$  compared to  $I\kappa B_{NS}^{+/+}$  cells was determined within the five proliferation steps (right panel). Error bars display the s.e.m. of four independent experiments. Statistical analyses were performed by two-tailed Mann-Whitney U test; (\*)  $p < 0.05$ , (\*\*)  $p < 0.01$ , (\*\*\*)  $p < 0.001$ .

To determine whether other cytokines were also impaired, *in vitro* generated wildtype and  $I\kappa B_{NS}$ -deficient  $T_H17$  cells were enriched to obtain similar frequencies of IL17<sup>+</sup> cells (Figure 31). Comparing the cell composition directly after the  $T_H17$  cell polarisation (non-enriched, Figure 31A upper panel) to the enriched  $T_H17$  cells (Figure 31A lower panel) most cells, which did not undergo efficient  $T_H17$  polarisation, were removed. Additionally, the enrichment of  $I\kappa B_{NS}$ -deficient and wildtype  $T_H17$  cells resulted in similar frequencies of IL17A<sup>+</sup> cells (Figure 31).

**Figure 31: Enrichment efficiency of IL17A-secreting cells.** Naïve T cells were isolated by flow cytometry and cultured for 4 days under T<sub>H</sub>17-priming conditions. Prior to enrichment, the cells were stimulated with PMA/ ionomycin (3 h). The IL17A expressing cells were enriched using a mouse IL17 secretion assay. After the magnetic separation of IL17-secreting cells, IFN $\gamma$  and IL17A-producing cells were identified by flow cytometry. Representative dot blots are illustrated in (A), the upper panel shows the cells prior to enrichment and the lower panel the cells after enrichment. The frequency of IL17A<sup>+</sup> cells was analysed (B). Error bars display the s.e.m. and are representative for three independent experiments. Statistical analyses were performed by two-tailed Mann-Whitney U test; n.s.= not significant.

First, enriched T<sub>H</sub>17 cells were stimulated with PMA and ionomycin and the supernatant was used in a cytokine array membrane (Figure 32 and Figure 33A). This membrane revealed a reduced secretion of IL2, IL10, IL6 and MIP1 $\alpha$  by  $IkB_{NS}$ -deficient T<sub>H</sub>17 cells. Secondly, flow cytometry-based cytokine measurement verified the reduced expression of these cytokines in  $IkB_{NS}$ -deficient T<sub>H</sub>17 cells (Figure 33B-C). Furthermore, the effect of the  $IkB_{NS}$  deficiency on the cytokine mRNA expression in stimulated T<sub>H</sub>17 cells was analysed by qPCR (Figure 33D). While the expression of IL6 mRNA was hardly detectable (data not shown), the analysis of the mRNA expression exhibited an equal expression of IL2 and MIP1 $\alpha$  in both genotypes. However, the anti-inflammatory cytokine IL10 showed a reduced expression in  $IkB_{NS}$ -deficient compared to wildtype T<sub>H</sub>17 cells, indicating a regulatory function of  $IkB_{NS}$  to IL10 expression.

**Figure 32: Diminished cytokine secretion of  $I\kappa B_{NS}$ -deficient  $T_H17$  cells was indicated by cytokine array membrane.** Naïve T cells were isolated by flow cytometry and cultured for 4 days under  $T_H17$ -priming conditions. The IL17A expressing cells were enriched and stimulated with PMA/ ionomycin (4 h). The relative levels of several cytokines in the supernatant of  $I\kappa B_{NS}^{+/+}$  and  $I\kappa B_{NS}^{-/-}$   $T_H17$  cells were profiled with a cytokine array membrane from R&D. Membranes of two independent experiments are shown (**A** and **B**). The location of positive (pos.) and negative (neg.) controls and cytokines on the array membrane are indicated in (**C**).

**Figure 33: Verification of the diminished cytokine secretion of  $I\kappa B_{NS}$ -deficient  $T_H17$  cells.** Naïve T cells were isolated by flow cytometry and cultured for 4 days under  $T_H17$ -priming conditions. The IL17A expressing cells were used directly (**D**) or were enriched (**A-C**). After the stimulated with PMA/ ionomycin (4h), the relative levels of several cytokines in the supernatant of  $I\kappa B_{NS}^{+/+}$  and  $I\kappa B_{NS}^{-/-}$   $T_H17$  cells were profiled with a cytokine array membrane (**A**), by flow cytometry (**B-C**) or by qPCR (**D**). The summary of the cytokine array membrane is shown in (**A**). The cytokine concentration in supernatant was measured by a bead-based flow cytometry array (**B**). In (**C**) the relative amount of cytokines in  $I\kappa B_{NS}^{-/-}$   $T_H17$  cells was calculated from the cytokine concentrations shown in (**B**). The fold change of MIP1 $\alpha$ , IL10 and IL2 in  $T_H17$  cells was measured by qPCR and normalised to stimulated  $T_H17$  wildtype cells (**D**). Error bars display the s.e.m. of two (**A**), three (**D**) or four (**B-C**) independent experiments.

### 3.3 Function of I $\kappa$ B<sub>NS</sub> in autoimmunity and inflammation

#### 3.3.1 I $\kappa$ B<sub>NS</sub> deficiency mildly delayed the onset of EAE

Studies on the autoimmune disorder multiple sclerosis and its animal model experimental autoimmune encephalomyelitis (EAE), suggested a T cell-mediated autoimmune demyelination<sup>57,151–154</sup>. Hilliard *et al.* reported about the importance of the NF- $\kappa$ B signalling in the onset of EAE<sup>155,156</sup>. Both, NF- $\kappa$ B1-deficient as well as cRel-deficient mice are largely protected to EAE induction<sup>155,156</sup>.

**Figure 34: Mildly reduced progression of experimental autoimmune encephalomyelitis (EAE) in I $\kappa$ B<sub>NS</sub>-deficient mice.** EAE was induced in I $\kappa$ B<sub>NS</sub><sup>+/+</sup> (n=17) or I $\kappa$ B<sub>NS</sub><sup>-/-</sup> (n=18) mice by s.c. injection of MOG(35-55)-peptide and two subsequent i.p. injections of pertussis toxin. The clinical score for the mice was monitored over 40 days. The shown data are the mean of animals (A), male mice (B) or female mice (C). Error bars display the standard error of the mean of the mice of four independent experiments. Statistical analyses were performed by two-tailed Mann-Whitney U test; n.s.= not significant, (\*) p<0.05.

To identify the role of  $I\kappa B_{NS}$  in the formation of autoreactive myelin-specific T cells and the onset of EAE, the progression of this disease was monitored from the day of MOG(35-55)-peptide immunisation until day 40 (Figure 34). The first clinical symptoms could be monitored within the wildtype group 7 days after the immunisation.

$I\kappa B_{NS}$ -deficient mice exhibited a delayed onset of EAE symptoms, first appearing at day 10. However, this difference was exclusively found between male mice with a significant change at day 9 (Figure 34, middle panel). Indeed,  $I\kappa B_{NS}$ -deficient female mice showed a reduced progression of EAE compared to wildtype mice. Hence, because of the narrow phenotypical differences comparing  $I\kappa B_{NS}$ -deficient and wildtype mice in EAE further *in vivo* analysis were performed (e.g. colitis induction, *Citrobacter rodentium* infection).

### **3.3.2 $I\kappa B_{NS}$ deficiency results in impaired $T_H17$ development and high susceptibility to chronic gut inflammation**

High numbers of  $T_H17$  cells are detectable in the uninfected gut compared to other tissues<sup>44</sup>. Intestinal inflammation, such as ulcerative colitis or Crohn's disease induce even higher  $T_H17$  numbers, which accumulate in the gut and the surrounding lymphoid tissues<sup>157,158</sup>. It was reported previously that innate immune cells are the important players in the acute form of DSS-induced colitis<sup>159</sup>. However, next to B cells,  $T_H1$  and  $T_H17$  cells promote the progression of chronic colitis, which can be induced by multiple cycles of DSS feeding<sup>160</sup>.

To identify whether  $I\kappa B_{NS}$  deficiency affects the formation of  $T_H17$  cells and thereby contribute to the pathogenesis of colitis, in cooperation with Dr. Rainer Glauben and Dr. Anja A. Kühl from the Charité, Berlin (Germany), chronic colitis was induced in  $I\kappa B_{NS}$ -deficient and wildtype mice by multiple cycles of DSS feeding (Figure 35 and Figure 36). During the progression of colitis the  $I\kappa B_{NS}$ -deficient mice lost significantly more weight compared to wildtype (Figure 35A). However, the colon length was reduced similarly in both  $I\kappa B_{NS}$ -deficient and wildtype mice (Figure 35B). Even without DSS feeding, colon damage was increased in  $I\kappa B_{NS}$ -deficient compared to wildtype mice, whereas DSS fed  $I\kappa B_{NS}$ -deficient and wildtype mice showed no histological differences (Figure 35C-D). The frequency of  $IL17A^+$  T cells was decreased in  $I\kappa B_{NS}$ -deficient non-treated as well as DSS-treated mice compared to wildtype mice (Figure 36).

**Figure 35:  $I\kappa B_{NS}$ -deficiency results in a more efficient chronic inflammation of the gut during DSS-induced colitis.** DSS colitis was induced in  $I\kappa B_{NS}^{+/+}$  (n=6) or  $I\kappa B_{NS}^{-/-}$  (n=9) mice by three rounds of DSS feeding and as control three wildtype and five  $I\kappa B_{NS}$ -deficient mice received non-supplemented water. The normalised weight of mice during inflammation is shown in (A) and the length of colon in (B). Representative hematoxylin and eosin staining of colon section are shown in (C) (scale bar represents 100  $\mu$ m). The histological score is the sum of individual scores of inflammatory cell infiltration and tissue damage (D). The frequency of  $IL17A^+$  within the  $CD4^+$  T cell subset was analysed by flow cytometry staining of the colon (D). Horizontal lines in (A-D) represent the mean of animals and error bars display the standard error of the mean. Statistical analyses were performed by two-tailed Mann-Whitney U test; n.s.= not significant, (\*)  $p < 0.05$ .

**Figure 36: Reduced frequency of IL17A<sup>+</sup> cells in  $I\kappa B_{NS}$ -deficient mice during DSS-induced colitis.** In  $I\kappa B_{NS}^{+/+}$  (n=6) or  $I\kappa B_{NS}^{-/-}$  (n=9) mice DSS colitis was induced by three rounds of DSS feeding. As control three wildtype and five  $I\kappa B_{NS}$ -deficient mice got normal water only. The frequency of IL17A<sup>+</sup> Fxp3<sup>-</sup> cells within the CD4<sup>+</sup> T cell subset was analysed by flow cytometry staining of the LPL (**A** and **B**). Representative dot blots are shown (**A**). Horizontal lines in (**B**) represent the mean of animals and error bars display the standard error of the mean. Statistical analyses were performed by two-tailed Mann-Whitney U test; n.s.= not significant, (\*) p<0.05.

Due to the fact that the DSS colitis suggested an important role of  $I\kappa B_{NS}$  for T<sub>H</sub>17 cell development during gut inflammation, it was determined in cooperation with Dr. Rainer Glaubien and Dr. Anja A. Kühl from the Charité, Berlin (Germany) if T<sub>H</sub>17 cell development is also impaired in T cell based transfer colitis (Figure 37 and Figure 38).

**Figure 37: In transfer colitis  $I\kappa B_{NS}$ -deficient T cells are more efficient to induce inflammation of the gut.** Transfer colitis was triggered in RAG1<sup>-/-</sup> mice by adoptive transfer (i.p.) of freshly isolated CD4<sup>+</sup>CD25<sup>-</sup> T cells from  $I\kappa B_{NS}^{+/+}$  (n=35) or  $I\kappa B_{NS}^{-/-}$  (n=36) mice. As control some mice were injected with PBS (n=17) only. The normalised weight of the mice during inflammation is shown in (**A**) and the length of the colon at the sampling day is represented in (**B**). The histological score is the sum of individual scores of inflammatory cell infiltration and tissue damage (**C**). Horizontal lines in (**A-C**) represent the mean of animals and error bars display the standard error of the mean. Statistical analyses were performed by two-tailed Mann-Whitney U test; n.s.= not significant, (\*) p<0.05, (\*\*) p<0.01, (\*\*\*) p<0.001, (\*\*\*\*) p<0.0001.

Hence, naïve  $CD4^+CD25^-$   $I\kappa B_{NS}$ -deficient or wildtype T cells were injected into  $Rag1^{-/-}$  mice. During the progression of colitis the recipients of  $I\kappa B_{NS}$ -deficient T cells lost more weight compared to recipients of wildtype T cells (Figure 37A). Furthermore, recipients of  $I\kappa B_{NS}$ -deficient T cells showed a comparable colon length to wildtype group (Figure 37B), but the histological damage was significantly increased by the transfer of  $I\kappa B_{NS}$ -deficient T cells (Figure 37C). Above all, the T cell composition showed a drastic change after colitis induction by the transfer of  $I\kappa B_{NS}$ -deficient compared to wildtype T cells (Figure 38). On the one hand, a significantly reduced frequency of  $IL17A^+$  (Figure 38A) as well as  $IL17A^+IFN\gamma^+$  T cells (Figure 38C) in recipients of  $I\kappa B_{NS}$ -deficient T cells was observed. On the other hand, the frequency of  $IL17A^-IFN\gamma^+$  T cells (Figure 38B) was significantly increased in recipients of  $I\kappa B_{NS}$ -deficient cells, demonstrating the relevance of  $I\kappa B_{NS}$  for the formation of  $T_H17$  cells in the inflamed gut. Taken together, both DSS as well as transfer colitis revealed the necessity of  $I\kappa B_{NS}$  for the development of  $T_H17$  cells in gut inflammation.

**Figure 38: Less  $IL17A^+$  and  $IL17A^+IFN\gamma^+$  cells are induced during transfer colitis in  $I\kappa B_{NS}$ -deficient mice.** Freshly isolated  $CD4^+CD25^-$  T cells from  $I\kappa B_{NS}^{+/+}$  (n=35) or  $I\kappa B_{NS}^{-/-}$  (n=36) mice were injected (i.p.) to  $RAG1^{-/-}$  mice and thereby transfer colitis was triggered. Mice injected with PBS (n=17) only served as control. The frequency of  $IL17A^+$  (A),  $IFN\gamma^+$  (B) and double positive cells (C) within the  $CD4^+$  T cell subset was analysed by flow cytometry staining of the colon. Horizontal lines in (A-C) represent the mean of animals. Error bars display the s.e.m. Statistical analyses were performed by two-tailed Mann-Whitney U test; (\*) p<0.05, (\*\*) p<0.01, (\*\*\*) p<0.001, (\*\*\*\*) p<0.0001.

### 3.4 Mice defective in $I\kappa B_{NS}$ display a high susceptibility to *Citrobacter rodentium* gut infection associated with an impaired $T_H17$ development.

*Citrobacter rodentium* is a non-invasive pathogen, which establishes acute infections of the murine large intestinal mucosa<sup>161</sup>. To clear the infection, antibodies produced by B cells are required and the help of  $CD4^+$  T cells, especially  $T_H17$  cells, is needed to produce resolving antibody titres<sup>78,162</sup>.

**Figure 39:  $I\kappa B_{NS}$ -deficient mice are more susceptible to *Citrobacter rodentium* infection.**  $I\kappa B_{NS}^{+/+}$  or  $I\kappa B_{NS}^{-/-}$  mice were infected orally with  $1 \times 10^{10}$  *C. rodentium* expressing the *lux*-operon and analysed at day 10 post infection. The normalised weight of mice during the course of infection (A), the histological score after infection (B) and representative hematoxylin and eosin staining of colon section (C) are shown. Horizontal lines in (A-B) represent the mean of animals and error bars display the s.e.m. Data are representative for one experiment of at least three individual experiments (A) or were pooled from two individual (B) experiments with at least three mice per group. Statistical analyses were performed by two-tailed Mann-Whitney U test; (\*)  $p < 0.05$ .

In cooperation with Zuobai Wang (Institute for infection immunology, TWINCORE, Hannover, Germany) *Citrobacter rodentium* was administered orally to  $I\kappa B_{NS}$ -deficient and wildtype mice to clarify the function of  $I\kappa B_{NS}$  in  $T_H17$  cells during gut infection (Figure 39, Figure 40 and Figure 41). An impaired growth rate in  $I\kappa B_{NS}$ -deficient mice was observed after the inoculation of bacteria, since these mice gained less body weight than age-matched wildtype mice (Figure 39A). On day 10,  $I\kappa B_{NS}$ -deficient mice exhibited a significantly increased damage of the large intestine, demonstrated by strongly thickened colon and more hyperplasia compared to wildtype mice (Figure 39B-C).

**Figure 40: Extended bacterial load in *IkBNS*-deficient mice during *Citrobacter rodentium* infection.**  $1 \times 10^{10}$  *C. rodentium* expressing the *lux*-operon were used for oral infection of *IkBNS*<sup>+/+</sup> or *IkBNS*<sup>-/-</sup> mice. At day 10 post infection, the mice were analysed for the spread of bacteria. The analysis of the *C. rodentium* burden in stool (A) and the bacterial load in liver and spleen (B) are shown. After the infection of mice with *lux*-operon expressing *C. rodentium* the bacterial load in intestinal tract (E) or the whole mice (C+D) was measured *in vivo* by bioluminescence imaging (IVIS-CT) at the day of infection (day 0), day 5 as well as day 10 (C) or at day 10 only (E). Horizontal lines in (A-B) represent the mean of animals and error bars display the standard error of the mean. Data were pooled from at least three individual (A-B) experiments with at least three mice per group or data are representative for one experiment with two (E) three (C-D) mice per group. Statistical analyses were performed by two-tailed Mann-Whitney U test; n.s.= not significant, (\*)  $p < 0.05$ , (\*\*)  $p < 0.01$ .

The bacterial burden was slightly increased in the spleen (Figure 40B) and significantly increased in stool (Figure 40A) as well as liver (Figure 40B) of *IkBNS*-deficient mice. Furthermore, whole body imaging of both genotypes displayed an equal accumulation of luminescent bacteria in the gut at the day of infection, which similarly spread into the intestinal tract at day 5 (Figure 40C-D). On day 10, wildtype and *IkBNS*-deficient mice had a significantly different luminescence signal, which showed that *IkBNS*-deficient mice did not clear the *Citrobacter rodentium* infection in contrast to wildtype mice (Figure 40C-E).

**Figure 41: Altered cellularity in  $I\kappa B_{NS}$ -deficient mice upon *Citrobacter rodentium* infection.** At day 10 post infection,  $I\kappa B_{NS}^{+/+}$  (n=8) or  $I\kappa B_{NS}^{-/-}$  (n=10) mice administered orally with  $1 \times 10^{10}$  *C. rodentium* (expressing the *lux*-operon) were analysed. Cells from colon, spleen and mLN were isolated and measured by flow cytometry. Representative dot blots (pre-gated to  $CD4^+CD3^+$  cells) of the colon are shown in (A). The frequency of Foxp3<sup>+</sup> (B), IFN $\gamma$ <sup>+</sup> (C), IL17A<sup>+</sup> (D) and IL17A/IFN $\gamma$  double positive cells (E) within the  $CD4^+CD3^+$  T cell subset was analysed. Horizontal lines in (B-E) represent the mean of animals and error bars display the standard error of the mean. Data were pooled from three individual experiments with two to four mice per group (B-E). Statistical analyses were performed by two-tailed Mann-Whitney U test; n.s.= not significant, (\*)  $p < 0.05$ , (\*\*)  $p < 0.01$ .

Moreover, at day 10 systemic and mucosal tissues of both genotypes showed reduced frequencies of IL17A<sup>+</sup> T<sub>H</sub>17 and IFN $\gamma$ <sup>+</sup> IL17A<sup>+</sup> double positive cells, where both frequencies were slightly reduced in the mLN and significantly reduced in colon and spleen of  $I\kappa B_{NS}$ -deficient compared to wildtype mice (Figure 41D-E). Additionally, the frequencies of IFN $\gamma$ <sup>+</sup> T<sub>H</sub>1 cells were equal in mLN and colon, but significantly reduced in spleens from  $I\kappa B_{NS}$ -deficient compared to wildtype mice (Figure 41A-C). Furthermore, while the Treg cell frequencies of colon and mLN were equal in both genotypes, the Treg frequencies were significantly decreased in spleens from  $I\kappa B_{NS}$ -deficient compared to wildtype animals (Figure 41A-B). Altogether,  $I\kappa B_{NS}$  promotes the development of T<sub>H</sub>17 cells to fight intestinal pathogens, whereas its loss causes an exacerbated course of disease.

## 4 Discussion

### 4.1 The loss of I $\kappa$ B<sub>NS</sub> alters the development of B cells

Signalling via the transcription factor NF- $\kappa$ B is one of the key mechanism activated by pre-B cell receptor (BCR) and BCR signals in mature cells. The BCR signalling causes a rapid IKK $\beta$ -dependent translocation of NF- $\kappa$ B dimers from the cytoplasm into the nucleus. The major NF- $\kappa$ B dimer found in pre-B cells is p50/p65, which is largely replaced by p50/cRel heterodimers in mature B cells<sup>163</sup>. Hence, it is not surprising, that the disruption of NF- $\kappa$ B family members or NF- $\kappa$ B regulators impairs the BCR-mediated proliferation, survival and Ig class switching of B cells<sup>140,141,164–169</sup>. Feng *et al.* suggested that NF- $\kappa$ B activity is required for the overall survival of B cells in all developmental stages<sup>169</sup>. Furthermore, inhibition of NF- $\kappa$ B blocks B cell development at two checkpoints. First, NF- $\kappa$ B inhibition affects B cell differentiation at the pro-B to pre-B cell transition, secondly the survival as well as the maturation of transitional/ immature B cells into follicular B cells is affected in the periphery<sup>169</sup>.

Arnold *et al.* reported a fast induction of I $\kappa$ B<sub>NS</sub> after cross-linking of the BCR<sup>133</sup>. Due to this fact and because B cell proliferation and effector function depends on NF- $\kappa$ B activity, the function of I $\kappa$ B<sub>NS</sub> in B cells was analysed in this thesis. The number of B220<sup>+</sup> B cells was impaired in the bone marrow and the blood of I $\kappa$ B<sub>NS</sub>-deficient mice. In line with this finding, the group of Touma *et al.* described a mild reduction within the B cell (B220<sup>+</sup>) compartment in spleen and lymph nodes of 6 to 10 weeks old I $\kappa$ B<sub>NS</sub><sup>-/-</sup> mice<sup>128</sup>. Four years later, a more detailed analysis of I $\kappa$ B<sub>NS</sub>-deficient B cells was performed in 9 month old mice<sup>132</sup>. Compared to young mice, the development of I $\kappa$ B<sub>NS</sub><sup>-/-</sup> B220<sup>+</sup> cells in spleen and lymph nodes was more delayed and this reduction was most pronounced in the blood<sup>132</sup>. In contrast, Arnold *et al.* used I $\kappa$ B<sub>NS</sub>-deficient *N*-ethyl-*N*-nitrosourea (ENU)-mutagenised mice and observe an equal frequency of immature and mature B cells compared to wildtype mice<sup>133</sup>. However the mice used in this thesis and in the publication of Arnold *et al.* were younger than the one used by Touma *et al.*. Hence, one may suggest that the older the mice, the stronger the effect of I $\kappa$ B<sub>NS</sub> to the formation of B220<sup>+</sup> B cells. Furthermore, both groups described a severe reduction or the entire loss of B1 B cells in I $\kappa$ B<sub>NS</sub>-deficient mice<sup>132,133</sup>, as it was shown for the deficiency of NF- $\kappa$ B1 and cRel/ NF- $\kappa$ B1<sup>167</sup>. Additionally, the generation of MZ B cells is highly sensitive to the disruption of NF- $\kappa$ B.

Hence, even the deficiency of only one of the NF- $\kappa$ B subunits reduces the numbers of MZ B cells.<sup>164–166,168</sup> In mice deficient for I $\kappa$ B<sub>NS</sub> Touma *et al.* identified a delayed development of MZ B cells<sup>132</sup> and Arnold *et al.* a lack of the MZ B cell population<sup>133</sup> compared to wildtype mice. In contrast, in this thesis no changes of the MZ B cell subsets were observed. The mice used in the analysis of Touma *et al.* as well as in this thesis are from the lab of Linda K. Clayton. Hence, the differences in the MZ B cell formation may arise from the different age of the mice, another gating strategy or different housing conditions (e.g. microbiota).

It is possible, that the reduction of I $\kappa$ B<sub>NS</sub>-defective B220<sup>+</sup> cells is the result of an increased cell death rate. This hypothesis is substantiated by a previous study revealing that NF- $\kappa$ B1-deficient cells exhibit an enhanced mitogen-induced apoptosis<sup>141</sup>. Senftleben and colleagues observed an increased turnover of IKK $\alpha$ <sup>-/-</sup> B cells, which correlated with a higher rate of spontaneous apoptosis<sup>170</sup>. However, the knockdown of I $\kappa$ B<sub>NS</sub> within the B cell line A20 did not influence the sensitivity to apoptosis compared to wildtype A20 cells in this thesis. Nevertheless, Touma *et al.* and Arnold *et al.* identified a diminished B cell proliferation in response to LPS in spleens of I $\kappa$ B<sub>NS</sub>-deficient mice<sup>132,133</sup>. In addition, a dramatically reduced level of serum IgM was detected by Touma *et al.* as well as Arnold *et al.* in I $\kappa$ B<sub>NS</sub>-deficient mice. Hence, cytoplasmic IgM was not detectable by any of these groups, but surface IgM levels were increased in I $\kappa$ B<sub>NS</sub>-deficient compared with wildtype mice, suggesting a defect in IgM secretion. Furthermore, beside the reduction of IgM, levels of IgG3 was dramatically reduced in serum of I $\kappa$ B<sub>NS</sub>-deficient mice<sup>132,133</sup>. The class switching to the IgG3 heavy chain gene was dramatically impaired in I $\kappa$ B<sub>NS</sub>-deficient mice, which was underlined by the lack of IgG3 in serum<sup>132</sup>. In contrast to wildtype mice, no germinal centre (GC) formation could be detected upon the immunisation of I $\kappa$ B<sub>NS</sub>-deficient mice with sheep red blood cells<sup>132</sup>. This is in line with the impaired formation of GC B cells in IKK $\alpha$ <sup>-/-</sup> reconstituted as well as p52- RelB- and Bcl3-deficient mice<sup>164,165,168,170,171</sup>. In contrast, Arnold *et al.* observed normal GC formation in immunised I $\kappa$ B<sub>NS</sub>-deficient mice. Hence, Arnold *et al.* concluded that I $\kappa$ B<sub>NS</sub> is to a lesser extent required for the formation of GC or memory B-cell responses rather than for differentiation of extra follicular antibody-secreting cells<sup>133</sup>. Altogether, this thesis shows that I $\kappa$ B<sub>NS</sub> is a significant regulator of the formation of B220<sup>+</sup> B cells, but apparently has no impact in apoptosis sensitivity. Additionally, Touma *et al.* as well as Arnold *et al.* uncovered the crucial function of I $\kappa$ B<sub>NS</sub> in proliferation and immunoglobulin (Ig)

production of B cells as well as plasma cell differentiation<sup>132,133</sup>. Besides, the regulatory mechanism needs to be examined in detail and possible target genes of I $\kappa$ B<sub>NS</sub> in B cells remains to be elucidated.

#### 4.2 Novel isoform of I $\kappa$ B<sub>NS</sub> may arise from posttranslational modifications

Western blot analysis of the murine B cell line A20 or stimulated primary T cells revealed two 70 kDa I $\kappa$ B<sub>NS</sub> isoforms in addition to the known 35 kDa form. Upon stimulation of wildtype expanded CD4<sup>+</sup> T cells both I $\kappa$ B<sub>NS</sub> isoforms appeared with a similar increase over time as well as a comparable signal intensity. This is consistent with the previous report of Schuster *et al.* showing a 35 kDa I $\kappa$ B<sub>NS</sub> in the cytoplasm and the nucleus as well as a nuclear 70 kDa I $\kappa$ B<sub>NS</sub>, with a mildly stronger expression<sup>134</sup>. Cross-reactivity of the I $\kappa$ B<sub>NS</sub> antibody does not explain the appearance of the 70 kDa isoform because of the absence of both I $\kappa$ B<sub>NS</sub> isoforms in I $\kappa$ B<sub>NS</sub>-deficient cells. In addition, two monoclonal murine as well as two polyclonal rabbit I $\kappa$ B<sub>NS</sub> antibodies detected the expression of the I $\kappa$ B<sub>NS</sub> isoforms. Consequently, cross-reactivity of the antibodies could be ruled out. Furthermore, both the 35 kDa I $\kappa$ B<sub>NS</sub> form as well as the 70 kDa I $\kappa$ B<sub>NS</sub> form were stable to denaturation by urea. Therefore, posttranslational modifications were suggested to be responsible for the shift in the molecular mass. Reports about Bcl3, which has a high sequence similarity to I $\kappa$ B<sub>NS</sub>, revealed that Bcl3 can switch between a cytoplasmic as well as a nuclear isoform<sup>111,112,172</sup>. Furthermore, the effect of Bcl3 on p50 or p52 homodimers depends on the phosphorylation of Bcl3<sup>110,111</sup>. Bundy *et al.* demonstrated that the regulation of p52 homodimers by Bcl3 depends, additionally to phosphorylation status of Bcl3, on the concentration of Bcl3 to p52 dimers<sup>110</sup>. Accordingly, phosphorylated Bcl3 was not able to inhibit the binding of p52 to  $\kappa$ B-sites, not even at high Bcl3 concentrations<sup>110</sup>. In addition, even low concentrations of phosphorylated Bcl3 enhanced the binding of p52. On the other hand, the de-phosphorylation of Bcl3 efficiently inhibited the binding of p52 to  $\kappa$ B-sites<sup>110</sup>. In contrast, Caamaño *et al.* showed that Bcl-3 needs to be phosphorylated to increase the binding of p50 homodimers to  $\kappa$ B-sites<sup>111</sup>. Additionally, ubiquitination as well as the SUMOylation are two further potential mechanism for I $\kappa$ B<sub>NS</sub> modification. The ubiquitination can affect the cellular localisation as well as the interaction of proteins or signal for proteasomal degradation<sup>173</sup>. Massoumi *et al.* analysed mice lacking the deubiquitinating enzyme CYLD (cylindromatosis) and suggested a role in

inhibition of tumour formation as well as keratinocyte proliferation<sup>172</sup>. Hence, CYLD translocates to the perinuclear region and removes K63-linked polyubiquitin from Bcl3, which results in cytoplasmic remigration. Thereby CYLD inhibits the nuclear accumulation of Bcl3 and inactivates Bcl3<sup>172</sup>. The other strongly suggested modification of IκB<sub>NS</sub>, the SUMOylation is a mechanism at which a small ubiquitin-like modifier (SUMO) is covalently added to a protein. The SUMO modification of proteins is important in transcriptional regulation and can lead to the adjustment of protein expression via protein degradation in the nucleus as well as the cytoplasm<sup>174</sup>. The degradation of the cytoplasmic IκB protein, IκBα, depends on the ubiquitination of lysine 21 (K21). This ubiquitination targets the IκBα protein for proteasomal degradation. In contrast, the SUMOylation of K21 by attachment of SUMO-1 acts antagonistically and inhibits signal-induced NF-κB activation<sup>175</sup>. Instead, the integration of SUMO-2/3 mediates the formation of ubiquitin chains to IκBα. These SUMO-2/3-ubiquitin chains promote the proteasomal degradation of IκBα and the activation of NF-κB<sup>176</sup>. Hence, one may hypothesize that the predominantly nuclear location of the 70 kDa IκB<sub>NS</sub> isoform based on posttranslational modifications, which are also essential for the activity as well as the nuclear translocation of IκB<sub>NS</sub>.

In brief, posttranslational modifications of REL-subunits as well as atypical IκB proteins such as Bcl3 are essential steps, which regulate the NF-κB pathway. It remains to be clarified whether the 70 kDa IκB<sub>NS</sub> is the functional active isoform or if both regulate the NF-κB pathway antagonistically or synergistically. Therefore, the modification of the 70 kDa IκB<sub>NS</sub> isoform has to be identified by mass spectrometry to draw conclusions to the function of both IκB<sub>NS</sub> isoforms.

### **4.3 IκB<sub>NS</sub> is essential for T<sub>H</sub>17 development and enhances the expression of IL10**

The recent report of Schuster *et al.* revealed that IκB<sub>NS</sub> controls the development of thymic and induced Treg cells by regulating the induction of Foxp3. Hence, mice defective in IκB<sub>NS</sub> exhibit an accumulation of Treg precursor cells in the thymus, but a reduction of mature Treg cells. Although, the IκB<sub>NS</sub> deficiency did not affect the suppressor function of Treg cells, their number was significantly reduced.<sup>134</sup> For this reason, an increased formation of auto-reactive T cells in IκB<sub>NS</sub>-deficient mice was expected. Since it was

possible that, because of the reduction of mature Treg cells, not all developing autoreactive T cells were suppressed. This may led to an expansion of self-reactive cells and, thus, autoimmunity. Surprisingly, it becomes apparent that I $\kappa$ B<sub>NS</sub>-defective mice do not suffer from autoimmune symptoms<sup>128,131</sup>. Consequently, one aim of this thesis was to determine, whether I $\kappa$ B<sub>NS</sub> affects the activation, development or function of other T helper subsets as well.

In this thesis, it was observed that I $\kappa$ B<sub>NS</sub> does neither influence the activation of cytoplasmic signalling pathways nor cytoplasmic intermediates downstream of the TCR in CD4<sup>+</sup> T cells. Accordingly, the phosphorylation of tyrosine as well as the phosphorylation and expression of Erk, Akt, and p38 was equal in I $\kappa$ B<sub>NS</sub>-deficient and wildtype cells. Furthermore, I $\kappa$ B $\alpha$  was identically phosphorylated and degraded in both genotypes upon T cell activation. Thus, I $\kappa$ B<sub>NS</sub> does not affect proximal TCR signalling in *ex vivo* CD4<sup>+</sup> T cells. This is in line with the literature, showing normal activation of conventional T cells and thymocytes in I $\kappa$ B<sub>NS</sub>-deficient mice<sup>128,134</sup>. Furthermore, it is known that I $\kappa$ B<sub>NS</sub> itself has no DNA-binding motif. Instead atypical I $\kappa$ B proteins indirectly bind to the DNA via NF- $\kappa$ B transcription factors. For instance, I $\kappa$ B $\zeta$  associates with the NF- $\kappa$ B proteins p50 and p65<sup>117,119</sup>. I $\kappa$ B<sub>NS</sub> itself interacts with p50 and mildly with cRel<sup>127,129,134</sup>. Additionally, Kuwata *et al.* identified the function of I $\kappa$ B<sub>NS</sub> in macrophages. The loss I $\kappa$ B<sub>NS</sub> induces a prolonged NF- $\kappa$ B activation, indicating a function of I $\kappa$ B<sub>NS</sub> for termination of NF- $\kappa$ B activity<sup>131</sup>. In this study, the loss of I $\kappa$ B<sub>NS</sub> did not impair the expression of the NF- $\kappa$ B subunits cRel, RelB, p65, NF- $\kappa$ B1 and NF- $\kappa$ B2 in stimulated CD4<sup>+</sup> T cells. This suggests that I $\kappa$ B<sub>NS</sub> regulates the NF- $\kappa$ B binding activity to  $\kappa$ B sites via direct binding to different NF- $\kappa$ B subunits, preferentially to p50 or cRel as reported in Treg cells<sup>134</sup> or other promoter bound proteins. Thus, I $\kappa$ B<sub>NS</sub> might regulate the activity of promoters, which could be important for T helper cells. Consequently, the identification of I $\kappa$ B<sub>NS</sub>-binding partners and T cell-specific target genes are subject for further investigations.

A number of studies indicated, that the disruption of I $\kappa$ B<sub>NS</sub> does not affect the numbers of double-negative (DN), double-positive (DP), CD4 and CD8 single-positive cells *in vivo*<sup>128,133,134</sup>. Nevertheless, it was published by Touma *et al.* that *ex vivo* I $\kappa$ B<sub>NS</sub>-deficient CD4<sup>+</sup> and CD8<sup>+</sup> lymph node cells as well as thymocytes displayed a reduced proliferation upon the cultivation with anti-CD3 $\epsilon$  and anti-CD3 $\epsilon$  together with anti-CD28, however, specific CD4 subsets were not individually examined<sup>128</sup>. For this reason, the function of I $\kappa$ B<sub>NS</sub> in the pro-inflammatory T helper subsets, T<sub>H</sub>17 and T<sub>H</sub>1, was

investigated in this study. First of all, the expression of I $\kappa$ B<sub>NS</sub> in T<sub>H</sub>17 as well as in T<sub>H</sub>1 cells was identified. As previously reported<sup>127,134</sup>, the I $\kappa$ B<sub>NS</sub> expression by T<sub>H</sub>17 as well as T<sub>H</sub>1 cells was induced upon cell stimulation. In addition, it was investigated, that the atypical I $\kappa$ B protein I $\kappa$ B<sub>NS</sub> is an important factor during the development of naïve T cells to T<sub>H</sub>1 and T<sub>H</sub>17 cells *in vitro*, since fewer I $\kappa$ B<sub>NS</sub>-defective naïve T cells primed into T<sub>H</sub>17 cells undergo less proliferation cycles. This theory is supported by the observation that even the presence of naïve wildtype T cells could overcome the proliferation defect *in vitro*, suggesting that I $\kappa$ B<sub>NS</sub> function is T cell intrinsic. Interestingly, Okamoto *et al.* showed that I $\kappa$ B $\zeta$  regulates T<sub>H</sub>17 proliferation in a cell intrinsic way<sup>121</sup>. Thus it could be demonstrated in this thesis that next to I $\kappa$ B $\zeta$ , I $\kappa$ B<sub>NS</sub> is intrinsically involved into the development of T<sub>H</sub>17 cells *in vitro*. Notably, the expression of I $\kappa$ B<sub>NS</sub> was detected in stimulated T<sub>H</sub>1 and T<sub>H</sub>0 cells, as well. As a result of I $\kappa$ B<sub>NS</sub> deficiency impaired T<sub>H</sub>1 proliferation was identified and less T<sub>H</sub>1 cells were generated in *in vitro* polarisation. This finding further underlined the initial hypothesis that Treg reduction does not cause an autoimmune phenotype in I $\kappa$ B<sub>NS</sub>-deficient mice, since T<sub>H</sub>1 and T<sub>H</sub>17 proliferation was impaired. Of note, proliferation of I $\kappa$ B<sub>NS</sub>-deficient Treg cells is not altered<sup>134</sup>. Thus, I $\kappa$ B<sub>NS</sub> is as a key regulator of T<sub>H</sub>1 and T<sub>H</sub>17 cell proliferation.

In Treg cells I $\kappa$ B<sub>NS</sub> associates via p50 and mildly with cRel to the Foxp3 promoter and the conserved non-coding sequence 3 (CNS3) of the Foxp3 locus<sup>134</sup>. In contrast, an I $\kappa$ B<sub>NS</sub>-independent RNA expression of the master transcription factors Tbet and ROR $\gamma$ t were revealed in T<sub>H</sub>1 and T<sub>H</sub>17 cells. The recent report of Okamoto *et al.*, identifying a I $\kappa$ B $\zeta$ -independent expression of ROR $\gamma$ t in T<sub>H</sub>17 cells, too<sup>121</sup>. In addition, Okamoto *et al.* identified the binding of I $\kappa$ B $\zeta$  together with ROR $\gamma$ t to the IL17A promoter, inducing an enhanced expression of IL17A<sup>121</sup>. In this thesis the RNA as well as the protein expression of IL17A showed a divergent output. On the one hand, RT-PCR data indicate a equal expression of IL17A in stimulated cells. On the other hand, the IL17A protein expression was mildly reduced on per cell basis (MFI) in stimulated I $\kappa$ B<sub>NS</sub>-deficient compared to wildtype cells and, furthermore, qPCR analysis revealed a stronger, but not significant reduction. These differences may arise from varying effectiveness of cell activation or variable sensitivity of the used methods. Thus further analysis like the use of the same cells for all three analysis are necessary. Nevertheless, the loss of I $\kappa$ B<sub>NS</sub> mildly reduced the IL17A expression (qPCR and MFI analyses). This suggests that I $\kappa$ B<sub>NS</sub> may stabilise the expression of IL17A in T<sub>H</sub>17 cells, but is not an essential factor for this. Furthermore, the

RNA expression of IFN $\gamma$  was comparable in T<sub>H</sub>1 cells of both genotypes upon PMA/ionomycin stimulation. Additionally, the defect in I $\kappa$ B<sub>NS</sub> significantly reduced the MFI of IFN $\gamma$ . This suggests that a robust IFN $\gamma$  protein expression by T<sub>H</sub>1 cells is mediated by I $\kappa$ B<sub>NS</sub>. Furthermore, post-translational modifications may induce an affected stability of IFN $\gamma$  in I $\kappa$ B<sub>NS</sub>-deficient T<sub>H</sub>1 cells. Further studies demonstrated regulatory function of nuclear I $\kappa$ B proteins on cytokine expression. For instance, both I $\kappa$ B<sub>NS</sub> and I $\kappa$ B $\zeta$  regulates the expression of the cytokines IL6 and IL12p40 in macrophages, at which I $\kappa$ B<sub>NS</sub> inhibits and I $\kappa$ B $\zeta$  enhances the expression<sup>119,131</sup>. In this thesis, measurements of cytokine secretion revealed that I $\kappa$ B<sub>NS</sub> regulates of MIP1 $\alpha$ , IL6 and IL2 in *in vitro* polarised T<sub>H</sub>17 cells. However, the mRNA level of MIP1 $\alpha$ , IL6 and IL2 was comparable in both genotypes. Previous studies demonstrated that IL6 and IL2 are direct target genes of I $\kappa$ B<sub>NS</sub><sup>128,129,131</sup>. Hence, it is possible that I $\kappa$ B<sub>NS</sub> indirectly regulates the secretion or stability of IL6 and IL2, but is dispensable for the gene expression of these two cytokines in T<sub>H</sub>17 cells. Kuwata *et al.* identified impaired mRNA expression of IL10 in I $\kappa$ B<sub>NS</sub>-deficient macrophages upon LPS stimulation<sup>131</sup>. Consistent with this report, a decreased mRNA level as well as secretion of IL10 was detected in I $\kappa$ B<sub>NS</sub>-deficient T<sub>H</sub>17 cells in comparison to wildtype cells. This finding indicates that I $\kappa$ B<sub>NS</sub> positively regulates the expression of IL10 in T<sub>H</sub>17 cells. Furthermore, Hirotsami *et al.* reported that IL10-deficient mice do not express the two nuclear I $\kappa$ B proteins Bcl-3 and I $\kappa$ B<sub>NS</sub><sup>129</sup>. Additionally, IL10 treatment strongly induced the expression of I $\kappa$ B<sub>NS</sub><sup>129</sup>. This suggests that I $\kappa$ B<sub>NS</sub> and IL10 potentially regulate each other by a feedforward loop. Touma *et al.* reported that I $\kappa$ B<sub>NS</sub> binds together with some unknown DNA-binding proteins to the IL2 promoter and thereby regulates the IL2 expression<sup>128</sup>. Hence, further investigations are necessary to elucidate if IL10 expression is regulated by I $\kappa$ B<sub>NS</sub> binding to the IL10 promoter, as well.

Altogether, I $\kappa$ B<sub>NS</sub> is dispensable for NF- $\kappa$ B activity in T cells but drives the differentiation of T<sub>H</sub>17 as well as T<sub>H</sub>1 cells and is essential for IL10 expression by T<sub>H</sub>17 cells. In the future, the identification of I $\kappa$ B<sub>NS</sub>-binding partners in developing T<sub>H</sub>17 cells and the identification of T<sub>H</sub>17-specific target genes are subject for further investigations.

#### 4.4 T<sub>H</sub>17 formation is supported by IκB<sub>NS</sub> in the inflamed gut

The progression of experimental autoimmune encephalomyelitis (EAE) is mediated by T<sub>H</sub>1 and T<sub>H</sub>17 cells and signalling via NF-κB<sup>57,151–156</sup>. Due to the impaired proliferation of IκB<sub>NS</sub>-deficient T<sub>H</sub>1 and T<sub>H</sub>17 cells, it was suggested, that IκB<sub>NS</sub>-deficient mice are protected to EAE or at least develop a less severe course of disease. Hence, the sensitivity of IκB<sub>NS</sub>-deficient mice to the induction of clinical EAE symptoms was analysed. The loss of IκB<sub>NS</sub> delayed the onset of the disease in male mice. Similarly, at the beginning IκB<sub>NS</sub>-defective female mice were as sensitive as wildtype mice, but a reduced clinical score was observed during the course of disease. On the contrary, Okamoto *et al.* demonstrated that the disruption of IκBζ induce a T<sub>H</sub>17 intrinsic differentiation defect and a complete resistance to EAE induction<sup>121</sup>. It is conceivable, that the myelin-specificity of T cells upon EAE induction overcomes the proliferation defect of T<sub>H</sub>1 or/ and T<sub>H</sub>17 cells. Thus, further investigations are necessary to clarify if both T cell subsets proliferate similar in IκB<sub>NS</sub>-deficient and wildtype mice upon induction of EAE. Furthermore, it remains to be elucidated if the loss of IκB<sub>NS</sub> alters the T<sub>H</sub>1 and/ or T<sub>H</sub>17 cell infiltration into the central nervous system as well as the myelin-specificity.

It was previously reported that IκB<sub>NS</sub>-deficient mice are sensitive to acute DSS-induced colitis as well as transfer colitis, showing severe inflammation of the colon<sup>131,134</sup>. In this study, the DSS colitis led to a reduced number of IL17A<sup>+</sup> T<sub>H</sub>17 cells in IκB<sub>NS</sub>-defective compared to wildtype mice. In addition to the DSS colitis, the transfer colitis was performed. In this colitis model, the loss of IκB<sub>NS</sub> caused an increased susceptibility to inflammation. During the transfer colitis less IL17A<sup>+</sup> IFNγ<sup>-</sup> T<sub>H</sub>17 cells as well as IL17A<sup>+</sup> IFNγ<sup>+</sup> T cells developed from transferred IκB<sub>NS</sub>-deficient T cells, accompanied by an higher frequency of IFNγ<sup>+</sup> T cells. Furthermore, the histological score was increased in recipients of IκB<sub>NS</sub>-deficient T cells. Hence, IκB<sub>NS</sub> is not only an important regulator of T<sub>H</sub>17 cell priming *in vitro* but is also prominent during the development of T<sub>H</sub>17 and IL17A<sup>+</sup> IFNγ<sup>+</sup> T cells in mouse models of gut inflammation. Although both IκB<sub>NS</sub>-deficient T<sub>H</sub>1 and T<sub>H</sub>17 cells showed a proliferation defect *in vitro*, T<sub>H</sub>1 cell development was not affected during colon inflammation *in vivo*. This might be due to the severely reduced induction of Treg cells<sup>134</sup>, or indicates the presence of additional signals, which promote T<sub>H</sub>1 development *in vivo*.

Taken together, while IκB<sub>NS</sub> seems to be almost dispensable for the course of EAE, it is an important modulator in colitis. Nevertheless, IκB<sub>NS</sub> is circumstantial for the development

of T<sub>H</sub>1 cells in gut inflammation. Hence, one might assume that the formation of myelin-specific T<sub>H</sub>1 cells is unaffected by the loss of IκB<sub>NS</sub> and this may hide the effect of a proliferation defect of myelin-specific T<sub>H</sub>17 cells. Consequently, further experiments like an adoptive transfer of either T<sub>H</sub>1 or T<sub>H</sub>17 cells or a conditional T<sub>H</sub>17-specific knockout of IκB<sub>NS</sub> are necessary to elucidate the function of IκB<sub>NS</sub> in EAE. Still, the NF-κB pathway and especially the IκB-protein family members might be important targets for anti-inflammatory drugs.

#### **4.5 IκB<sub>NS</sub> promote the development of T<sub>H</sub>17 cells in *Citrobacter rodentium* gut infection**

To corroborate the previously described findings, mice were challenged with *Citrobacter rodentium*, which colonise the large intestine with a peak of infection at day 10. An elevated sensitivity of IκB<sub>NS</sub>-deficient mice to *Citrobacter rodentium* infection was observed, associated with an increased bacterial burden and histological score. As demonstrated in the in vitro and the colitis experiments, IκB<sub>NS</sub>-deficient T cells showed a reduced development in colon and spleen of infected mice. While the regulatory effect of IκB<sub>NS</sub> in T<sub>H</sub>1 cells was only mild, IκB<sub>NS</sub> was an important factor for T<sub>H</sub>17 as well as IL17A<sup>+</sup> IFNγ<sup>+</sup> cell generation in gut infection. Symonds *et al.* recommend a role of Treg cells in *Citrobacter rodentium* infection, because of an increased induction of Foxp3<sup>78</sup>. The recent report on the function of IκB<sub>NS</sub> in Treg cells indicated the importance of IκB<sub>NS</sub> for the transition of Treg precursors (GITR<sup>+</sup>CD25<sup>+</sup>Foxp3<sup>-</sup>) to mature Treg cells in the thymus. In this report, Schuster *et al.* demonstrated a reduction of mature Treg cells in IκB<sub>NS</sub>-deficient mice<sup>134</sup>. After the infection of IκB<sub>NS</sub>-deficient mice with *Citrobacter rodentium* Treg frequencies were reduced in systemic tissues (spleen) compared to wildtype mice, as well. However, the deficiency of IκB<sub>NS</sub> did not affect the frequency of Treg cells in the infected colon or mesenteric lymph nodes. Hence, it is conceivable that *Citrobacter rodentium* infection induces extrinsic or intrinsic factors, which overcome the IκB<sub>NS</sub>-deficiency, but are irrelevant for thymic Treg development. Alternatively, *Citrobacter rodentium* infection might enhance the Treg migration into the gut. A further explanation could be the increased formation of inducible Treg (iTreg) cells in the gut of infected IκB<sub>NS</sub>-deficient mice. This raised iTreg-formation is maybe mediated by ghrelin. Ghrelin was found in IBD patients<sup>177</sup>, TNBS-induced mice colitis<sup>178</sup> and

*Citrobacter rodentium* infections<sup>78</sup>, where it was suggested to induce the expression of Foxp3. In line with the responses in I $\kappa$ B<sub>NS</sub> wildtype mice, it was previously reported that infection with *Citrobacter rodentium* predominantly induces T<sub>H1</sub> and T<sub>H17</sub> cells<sup>78,179,180</sup>. The idea of a T<sub>H1</sub>-dependent defence to *Citrobacter rodentium* is supported by the induction of IL12, IFN $\gamma$  as well as TNF $\alpha$  expression during infection<sup>179</sup>. On the other hand, Symonds *et al.* suggested a T<sub>H17</sub> response, supported by the finding of only minimal changes in the T<sub>H1</sub> pathway together with an increased expression of IL6, IL17 and TNF $\alpha$ , which is suggested to amplify the T<sub>H17</sub> response. Furthermore, it was shown by McGeachy *et al.*, that IL10 is expressed by T<sub>H17</sub> cells generated with TGF $\beta$  and IL6. This IL10 co-expression by T<sub>H17</sub> cells is supposed to be a self-regulating mechanism to minimise the inflammatory damage of T<sub>H17</sub> cells<sup>85</sup>. The reduced expression of IL10 by I $\kappa$ B<sub>NS</sub>-deficient T cells may lead to a reduced self-regulation of T<sub>H17</sub> cells. This implies an increased bystander inflammatory damage induced by T<sub>H17</sub> cells. Nevertheless, it remains to be clarified if the loss of I $\kappa$ B<sub>NS</sub> also induces T<sub>H17</sub> cells expressing less IL10 during infection.

#### 4.6 Concluding remarks

The transcription factor NF- $\kappa$ B is an important regulator in T cell activation, proliferation and survival and, thus, basic requirement for effective immune responses. Therefore, it is crucial to understand the regulation of NF- $\kappa$ B in immune cells, inflammatory as well as infectious diseases to design effective treatments. In this thesis, it was investigated that beside the nuclear I $\kappa$ B protein I $\kappa$ B $\zeta$ , I $\kappa$ B<sub>NS</sub> is an essential regulator in adaptive immunity, demonstrated by its supportive function in T<sub>H17</sub> cell differentiation.

I $\kappa$ B<sub>NS</sub> does not affect the proximal TCR signalling and the expression of NF- $\kappa$ B subunits in *ex vivo* CD4<sup>+</sup> T cells. In addition, an I $\kappa$ B<sub>NS</sub>-independent expression of the master transcription factors ROR $\gamma$ t in T<sub>H17</sub> cells as well as Tbet in T<sub>H1</sub> was revealed. Interestingly, I $\kappa$ B<sub>NS</sub> is an important modulator during the polarisation of naïve T cells to T<sub>H1</sub> and T<sub>H17</sub> cells *in vitro* and *in vivo*. Additionally, I $\kappa$ B<sub>NS</sub> is intrinsically involved in the development of T<sub>H1</sub> and T<sub>H17</sub> cells, as it was shown for I $\kappa$ B $\zeta$ <sup>121</sup>, although the molecular mechanism needs to be decoded more detailed. Furthermore, I $\kappa$ B<sub>NS</sub> is an essential regulator of IL10 expression by T<sub>H17</sub> cells. *In vivo*, I $\kappa$ B<sub>NS</sub> seems to be dispensable for the course of EAE, while it is crucial for the formation of T<sub>H1</sub> and T<sub>H7</sub> cells in gut

inflammation as well as infection. Furthermore, I $\kappa$ B<sub>NS</sub> modulates the T<sub>H</sub>17 cell induction, while it is less important for T<sub>H</sub>1 cell development during inflammation and infection of the gut.

In the future, the following open questions should be addressed by additional investigations. Firstly, it remains to be clarified if I $\kappa$ B<sub>NS</sub> binds to the IL10 promoter and thereby regulate IL10 expression, as it was shown for IL2<sup>128</sup>. Secondly, further analyses are necessary to elucidate if I $\kappa$ B<sub>NS</sub> is also an important modulator of IL10 expression by T<sub>H</sub>17 cells in infections. Finally, the identification of I $\kappa$ B<sub>NS</sub>-binding partners in developing T<sub>H</sub>17 cells as well as T<sub>H</sub>17-specific target genes are of major importance on the molecular level.

In conclusion, I $\kappa$ B<sub>NS</sub> not only enhances thymic Foxp3 induction and thereby the development of immuno-suppressive Treg cells, but is also necessary for the generation of pro-inflammatory T<sub>H</sub>17 cells *in vitro* and *in vivo*. Thus, I $\kappa$ B<sub>NS</sub> exhibits diverse regulatory functions for T cell proliferation and cytokine secretion. Consequently, I $\kappa$ B<sub>NS</sub> may represent a T cell specific pharmacological target in the future.

## 5 Abbreviations

APC	antigen-presenting cell
ARD	ankyrin repeat domain
BCR	B cell receptor
CD	Cluster of differentiation
CFSE	Carboxyfluorescein succinimidyl ester
CMJ	Corticomedullary junction
CNS3	Conserved non-coding sequence 3
cTECs	cortical thymic epithelial cells
DC	Dendritic cell
DN	Double negative (CD4 <sup>-</sup> CD8 <sup>-</sup> )
DNA	deoxyribonucleic acid
DP	Double positive (CD4 <sup>+</sup> CD8 <sup>+</sup> )
EAE	Experimental autoimmune encephalomyelitis
FCS	Fetal calf serum
Foxp3	Forkhead box protein 3
GITR	Glycocorticoid-induced TNF receptor
GRR	Glycine rich region
HSC	hematopoietic stem cell
IBD	Inflammatory bowel disease
IFN $\gamma$	Interferon $\gamma$
Ig	Immunoglobulin
IKK	I $\kappa$ B kinase
IL	Interleukin
IL23R	Interleukin 23 receptor
IRF4	Interferon regulatory factor 4
I $\kappa$ Bs	Inhibitor of NF $\kappa$ B protein
LPS	Lipopolysaccharide
m	mouse
MHC	Major histocompatibility complex
mLN	mesenteric lymph nodes
mTEC	Medullary thymic epithelial cell
NF- $\kappa$ B	Nuclear factor $\kappa$ B

---

NIK	NF- $\kappa$ B inducing kinase
NLS	Nuclear localisation signal
PAMP	Pathogen-associated molecular pattern
PCR	Polymerase chain reaction
pLN	peripheral lymph nodes
PMA	phorbol-12-myristate-13-acetate
PRR	Pattern recognition receptors
qPCR	Quantitative real-time detection PCR
RAG1	Recombination activating gene 1
rb	rabbit
RHD	REL-homology domain
RNA	ribonucleic acid
ROR $\gamma$ t	Retinoic-acid-receptor-related orphan receptor- $\gamma$ t
Runx1	Runt-related transcription factor 1
SCZ	subcapsular zone
SFB	Segmented filamentous bacteria
shRNA	short hairpin RNA
SP	Single-positive
STAT	Signal transducer of activated T cells
SUMO	Small ubiquitin-like modifier
TAD	Transcription activation domain
TCR	T cell receptor
TGF $\beta$	Transforming growth factor $\beta$
T <sub>H</sub> cell	T helper cell
TNF $\alpha$	Tumor necrosis factor $\alpha$
Treg	Regulatory T cell
TSPs	thymus-settling progenitors

## **7 Acknowledgments**

First of all I want to thank my supervisor Prof. Dr. Ingo Schmitz for giving me the opportunity to work on this interesting and challenging project. Particularly, I want to thank him for the willingness to share his scientific expertise, for helpful discussions and support as well as the kind atmosphere.

I also want to thank colleagues Frida, Yvonne, Sabrina, Svenja, Alisha, Neda, Daniela, Tanja, Stephanie, Marc, Carlos, Tobias and Ralf for the pleasant and helpful atmosphere in the lab.

I am deeply grateful to my family and friends, especially my mother Christine, my father Ralf, my sister Nicole and my friend Kerstin for all the support they provided me through my entire life and for the interest in my work.

Finally, I want to thank Thomas for his affectionately support, helpful suggestions, tolerance and love.

## **8 Declaration of originality**

Michaela Annemann  
Robert-Koch-Straße 6  
38106 Braunschweig

Hiermit erkläre ich, dass ich die von mir eingereichte Dissertation zu dem Thema

### **“Functional studies on the role of I $\kappa$ B<sub>NS</sub> in T helper cell differentiation”**

selbständig verfasst, nicht schon als Dissertation verwendet habe und die benutzen Hilfsmittel und Quellen vollständig angegeben wurden.

Weiterhin erkläre ich, dass ich weder diese noch eine andere Arbeit zur Erlangung des akademischen Grades doctor rerum naturalium (Dr. rer. nat.) an anderen Einrichtungen eingereicht habe.

Magdeburg, den 18.12.2013

Michaela Annemann

## 9 Curriculum vitae

### Persönliche Daten

Name: Michaela Annemann  
 Geburt: 14.08.1983  
 Geburtsort: Neindorf-Beckendorf  
 Familienstand: ledig  
 Nationalität: deutsch

### Bildungsweg

1990-1991 Oberschule Eilsleben  
 1991-1994 Grundschule Ummendorf  
 1994-2003 Allertal- Gymnasium Eilsleben/ Völpke  
 2003-2009 Diplomstudium der Biologie, Technische Universität  
 Braunschweig  
 10/08-09/09 Diplomarbeit am Helmholtz- Zentrum für Infektions-  
 forschung, Braunschweig mit dem Thema "Characterisation  
 of the novel adjuvants PQS and PQSMPEG"

### Wissenschaftliche Tätigkeit

01/10 Beginn der Dissertation am Helmholtz- Zentrum für  
 Infektionsforschung, Braunschweig in der AG von Prof. Dr.  
 Ingo Schmitz

### Sonstiges

11/09 Erwerb des Fachkundenachweises gem. §9 des Tierschutz-  
 gesetzes

### Veröffentlichungen
